EDITORIAL PREFACE

If it had not been for the World War, there would not have been any occasion, so early as 1922, for a Supplement to the Eleventh Edition of the *Encyclopædia Britannica*, as published in 1911. But for the exceptional situation so created, the original intention not to take in hand anything equivalent to a Twelfth Edition until a much later date would undoubtedly have been maintained.

So colossal a convulsion, however, as that of the war, with consequences shown in so many unexpected directions and radically changing the world-outlook under the new conditions, made the need for this prompt addition to universal history absolutely imperative, as a record and illumination of so peculiarly dark and complex a period. The gap between 1911 and 1921 is all the more noticeable because, from the middle of 1914 onwards, authentic history could not be written at all, as had been practicable normally under earlier peace conditions, in such periodical publications as have usually served the requirements of the public for purposes of reference on contemporary affairs. The very nature of the war, and of the war conditions which persisted even after the Armistice, not only involved the imposition of secrecy, the cutting off of intercommunication, and even an interested perversion of fact in much that was given out for belief, but also led to a state of paralysis and aphasia in the spheres where, before the war, independent observation and judgment were to be found. Attention was monopolized everywhere by conditions of urgency and emergency, and concentrated upon the immediate conduct of life, while almost every expert, whether in scholarship or in science, was living, so to speak, from hand to mouth, with his accustomed intellectual activities interrupted, suspended, or diverted.

In such circumstances there arose inevitably a clear call for the publication of a Supplement to the *Encyclopædia Britannica* at as early a date as was practicable after the war, conformably with the arrival of a stage in post-war reconstruction which would once more enable its Editor to secure a reasonable modicum of the disinterested international cooperation on which the value of the *Encyclopædia Britannica*, as a critical record of world-history, has so long depended.

These New Volumes of the *Encyclopædia Britannica* accordingly follow precedents established during the 154 years since it made its first appearance in 1768. Between its Third (1788–97) and Fourth (1801–10) Editions, a two-volume Supplement (1801) to the Third Edition was published; and while the Fifth Edition (1815–7, a reprint of the Fourth) was still current, and the reedited Sixth (1823–4) was nearly ready for issue, a "Supplement to the Fourth, Fifth and Sixth Editions," edited by Macvey Napier, appeared in six volumes during 1816–24. In 1902 again, by way of supplement to the Ninth Edition (1875–89), there were published eleven New Volumes, forming in combination with it the Tenth Edition, for the general editorship of which the present writer, taking over the task early in 1900 from the late Sir Donald Mackenzie Wallace, was responsible. Incidentally
those eleven New Volumes set a new precedent in publications of this kind by being prepared and issued simultaneously, and the same method was subsequently adopted in the preparation of the Eleventh Edition (1911).

Had it not been for the war, the twenty years between the average date of the Ninth Edition (25 Volumes, 1875-89) and the date of its supplementary New Volumes, which were added to form the Tenth Edition (1902), may be regarded as indicating the length of interval which might well have been expected to follow the publication of the Eleventh Edition before it in turn had a supplement added to it, to form in combination with it the Twelfth Edition. The course now taken, however, is directly in line with Macvey Napier’s great Supplement (1816–24) to the Fourth, Fifth and Sixth Editions. The extent of that Supplement exhibited, indeed, a notable advance in the whole standard of the Britannica as a work of original scholarship and expert authority—the result of the copyrights having recently passed into the hands of the enterprising publisher Constable: but its interest in this particular connexion lies in the fact that it was conceived as a response to the pressing demand for a comprehensive survey of the situation resulting from the Great War which had just ended at Waterloo in 1815. In 1816, when the first volume of Macvey Napier’s Supplement appeared, the same need was felt for an authoritative record and reconsideration of the new developments during the convulsions of 1793–1815 as has arisen now in respect of the decade ending with 1921, and for very similar reasons. Anyone who still cares to examine that remarkable Supplement of 1816–24 will find that the ideals of public service in education set before themselves by Constable and Macvey Napier (as expressed by the latter in his Preface to the Sixth Volume) were identical with those which animate the Encyclopædia Britannica to-day. The present writer, having made this examination, with knowledge of the many difficulties of his own task a hundred years later (on the first subsequent occasion of an engrossing conflict having upset the world), is bound to testify to the admirable way in which, amid evidence of similar obstructions and complications, Macvey Napier carried out his scheme. His Supplementary Volumes, organized at the conclusion of the Great War of 1793–1815, formed the only critical and universal survey then available of the period just ended. They brought together a mass of valuable material which was afterwards incorporated in later editions; indeed much of this information, fresh from the sources, could only have been placed on record by being obtained at that time—a consideration which is encouraging to the Editor of the present New Volumes in regard to the permanent value of the material embodied in them also.

In one respect, possibly, Macvey Napier may appear to have had an advantage over the present Editor, or a somewhat easier task, in that he had eight years over which to spread the publication of his volumes—first issued in parts. But his successor a hundred years later is too conscious of the real advantage given to the public by immediate and simultaneous production, and indeed of the superior quality which such a work possesses when the whole of it has been under editorial control at one time, to take this superficial view. Having himself organized the production of these New Volumes within a single year—a year, moreover, characterized by post-war unrest and unsettlement—he may perhaps make this difference of method some excuse, however, for any imperfections in them which may be found in the light of later events or of knowledge undisclosed
while they were in the making. The generous reader may pardon some incidental defects or omissions, in consideration of his having the use, practically at once, of the full Supplement, as complete as it could reasonably be made, and not having to wait several years for a succession of volumes with long intervals between them. In the latter case each volume would be apt to exasperate him by cross-references from its articles to others in a volume still inaccessible; each earlier one, furthermore, would become relatively out-of-date as soon as the next one appeared; and the whole must lack organic unity, because the subject-matter, as distributed in one volume or another, must necessarily have been dealt with at different dates from dissimilar viewpoints.

These New Volumes, systematically arranged, in accordance with the traditional standards of the Encyclopedia Britannica, so that the articles may be adapted either for continuous reading or for occasional reference, have been planned as a guide to an appreciative understanding of contemporary affairs. The reader has before him what may be described as an international stock-taking, by carefully selected authorities, of the march of events all over the world from 1909-10 to 1920-1, and of the nature and critical value of such advances as were made in the principal branches of knowledge during that period. In this respect the New Volumes aim at giving a key to the problems of to-day, so far as these contemporary problems are bound up—as indeed they are to an unprecedented extent—with the new social and economic issues which only began to emerge in their present magnitude, or to impress themselves on the public, as the result of the tremendous upheaval caused by the World War. Yet it is necessary, in the interests of a publication which is essentially educational, to add one proviso. It remains as true as ever that contemporary human life and interests are organically related not only to the immediate developments of one preceding decade but to those of a succession of earlier decades and epochs, back to the abysses of time. The great Drama is of the Ages, and can only be appreciated with all its Acts on record. The eye which looks only at the passing scene is too often colour-blind. The roots of the Post-War World go down into the Pre-War World. Its proper interpretation can be found only in the light of all that earlier history on which we can look back—as we cannot do on contemporary affairs—with assurance that it is seen in perspective and in ordered values, as the result of an accumulation of disinterested criticism. The Post-War World is the residuary legatee of the Pre-War World, from which it inherits the whole basis of its intellectual equipment. The present survey of recent happenings, indispensable though it may be as an account of the Post-War World, can only therefore be utilized perfectly when it is regarded as an integral part of the unitary library of education represented in all the thirty-two volumes now forming the complete Twelfth Edition. The structure of that great edifice, with its contents, is not substantially affected by the fact that it has been built with an Annexure for housing more recent

1 It may be noted here that, though bibliographical references, representing a selection of the most authoritative books or documents published since 1910, are plentifully made in the New Volumes, it was impossible, merely by way of supplement to the bibliographies attached to articles in the Eleventh Edition, to include them systematically, except in appropriate cases where this course was demanded by the nature of the supplementary articles. No attempt has been made, when otherwise there was no substantial reason for adding a supplementary article at all to the account given of a subject in the Eleventh Edition, to add a list of later books published about it. Nor, indeed, in the Editor's judgment, would it have been in accordance with the objects of the Britannica to give the cachet of "authority" in this way to many contemporary publications which can hardly be said to have earned that title. The bibliographical references in the Britannica are especially valuable as critically directing the reader to the best sources, outside its own articles, for more detailed information; but the very nature of many of the articles in the New Volumes, as being the latest (or even the only available) authoritative accounts of purely contemporary developments, made it unnecessary—if indeed it would not be misleading—to direct the reader to comparatively ephemeral publications by less responsible writers.
acquisitions, in the shape of these New Volumes. They are designed as having behind or beside them the main body of the work—the earlier Volumes of the Eleventh Edition which were constructed in the closing years of the Pre-War World.

It may be pardonable for the present writer, at the end of the twenty-first year of his occupancy of the position of Editor of the *Encyclopædia Britannica*, to emphasize in retrospect one specially valuable characteristic of the Eleventh Edition, in supplying to-day an authoritative digest of world history and the progress of knowledge up to the last few months before it was originally published in 1911. Its value does not merely depend on the benefit secured to the reader of these New Volumes by its having also been produced as a whole at one date, so that its accounts of every subject, organically distributed under appropriate headings, represent uniformly a single editorial policy (identical with that of to-day), a common terminus of time in the facts dealt with, and a common standard of criticism in the viewpoints of its contributors—so far as expert opinion at any one moment is ever in agreement. This in itself is, no doubt, a great convenience in the linking up of the later information provided in the New Volumes. But there is a still more important quality attaching to the Eleventh Edition, of which indeed its Editor was not himself fully aware during the critical years of its preparation. It required the experience obtained during the gestation of these New Volumes to teach the Editor how much simpler a matter it is to create such a "Library of Education" when the world is at peace and is progressing normally, as it was in the years preceding 1911, than when, as recently, it is everywhere in convulsion, nobody being able to tell from week to week what he would be doing next, or where some new complication or even revolution, political, economic, industrial or scientific, might break out, to the upsetting of any attempt at orderly statement of the progress of events and the crystallization of opinion. Though it was not so realized at the time, it is now evident that the maximum service which the *Encyclopædia Britannica* could have performed for the public of to-day was the production of the Eleventh Edition in 1911, before the war of 1914-9 cut a Grand-Canyon gash in the whole intellectual structure of the world. For what would have happened if the complete new edition which would follow the Tenth Edition had not been undertaken until several years later—say, after the Armistice? In that case it would still have been necessary, in some way, to keep what may roughly be divided as the Pre-War and Post-War Worlds distinct. The account of the Post-War World would then substantially be what appears in the present New Volumes; for this must, in any case, start at a convenient point before the war, in order to make the break intelligible, and it must differ in scope and perspective from the part devoted to the Pre-War World, in proportion as its new problems require a different sort of discussion according to their bearing on the future rather than as continuations of past history. But so far as the Pre-War World is concerned—everything, that is to say, except the contemporary developments of the decade preceding 1921—it may be asserted, without fear of contradiction from anyone who can appreciate the responsibilities of an Editor of the *Encyclopædia Britannica*, that, if the task had not been undertaken till after 1914, it would have been absolutely impossible to produce to-day anything so comprehensively authoritative or critically complete as is actually available in the shape of the Eleventh Edition owing to its having been produced just before the war.

1Reference by volume and page (e.g. "see 2,403") is accordingly made, as a rule immediately after the headings of articles in the New Volumes (but also elsewhere in their course, as seemed useful), to places in the earlier volumes where accounts of the same subjects, leading up to the point where the account is now resumed, may be found.
EDITORIAL PREFACE

In the present writer's judgment it is very remarkably the fact that, however carefully the contents of the Eleventh Edition are tested, as representing the highest standards of international research and criticism, whether in Science or in Art or in historical information, up to 1911, nothing substantial has occurred since to diminish its value or alter its perspective. The reason is that it was fortunately produced at a quiet period, when there was every opportunity for obtaining sure, authoritative and orderly surveys, in a world-society which was evolving along known lines of "normalcy"—to use President Harding's favourite expression—fairly calculable in advance in accordance with well-informed expectations, and permitting of a reasonably final judgment on the sequence of contemporary progress in relation to the past. To-day, on the other hand, the whole atmosphere of scholarship and thought has temporarily been vitiated by the world upheaval, and the cooperation enlisted for the Eleventh Edition is unattainable under present conditions. It is not too much to say that the service done by the *Encyclopædia Britannica* for the public, by bringing together in the Eleventh Edition its unique combination of the world's ripest judgments on every sort of subject, could not have been rendered to this generation at all if that Edition had not been completed before the war. As the composition of the present New Volumes shows, it has still been possible for the Editor to enlist the most highly qualified experts, and writers officially connected with Government Departments or Services, for dealing with matters familiar to them (and often known only to them) in the course of the past decade. But the writing of contemporary history by persons who have been chief agents or eye-witnesses is one thing; it is quite another to recreate the whole drama of the far-reaching past. To do that, as it was done in the Eleventh Edition, needs a type of mind and will which for the present has largely ceased to function along the pre-war ways.

Irrespectively, indeed, of the question whether as good a complete edition as the Eleventh could have been produced *de novo* now, it would cost in any case at least twice as much to make as it did in 1911, and it would have to be sold at a far higher price. But, from the editorial point of view, the important fact is that it could not be made to-day so as to have anything like the scholarly value of the work produced before the war by the contributors to the Eleventh Edition. Neither the minds nor the wills that are required for such an undertaking are any longer obtainable in any corresponding degree, nor probably can they be again for years to come. This is partly due to sheer "war-weariness," which has taken many forms. A shifting of interest has taken place among writers of the academic type, so that there is a disinclination to make the exertion needed for entering anew into their old subjects—a necessary condition for just that stimulating, vital presentation of old issues in the light of all the accumulated knowledge about them, which was so valuable a feature of the Eleventh Edition; the impulse has temporarily been stifled by the pressure of contemporary problems. Many of the pre-war authorities, moreover, have died without leaving any lineal successors, and others have aged disproportionately during the decade, while the younger generation has had its intellectual energies diverted by the war to work of a different order. Again (a most essential factor), it would have been impossible to attain the same full measure of international coöperation, among representatives of nations so recently in conflict, and in a world still divided in 1921 by the consequences of the war almost as seriously as while hostilities were actually raging.
It is with some satisfaction that the Editor has been able to make a fresh beginning in these New Volumes toward a revival of this cooperation, by including German, Austrian and Hungarian contributors, in addition to those from the countries allied or associated with the British Empire and the United States during the war. In the material structure of the New Volumes, and their sub-editing, the same note of Anglo-American solidarity is struck as in the Eleventh Edition; and this is again emphasized by their being dedicated jointly to the two Heads of the English-speaking peoples, by express permission of King George V. and President Harding. Nowhere except in Great Britain and the United States would it have been possible, under the world-conditions of 1921, to find the standard of poise and perspective required in their construction. Any other assumption, throughout these New Volumes, than that the terrible war of 1914-9 was won by those who had right and justice for their cause, would manifestly be impossible in the Encyclopædia Britannica; and historical justification for this belief is indeed given in the proper articles. On the other hand, many of the more violent criticisms of German action current during the war are now shown, in the Anglo-Saxon spirit of fair play, to have been exaggerated for "propaganda" purposes. Opinion on the incidents and issues of the war-period will probably continue to be revised by succeeding generations over and over again, as the weight of evidence, so much of it still undisclosed, increases; but a start is made here toward the acceptance of such conclusions as already represent a judicial view, expressed without favour or malice, free from any conscious bias, and backed by a presentation of the relevant facts on authority that is either admittedly unimpeachable or so far unchallenged. It was an integral part of the editorial policy to put aside any war-prejudice in inviting the assistance of contributors from among the nations which had fought against the Allies, so far as might be practicable without the intrusion of "propaganda," especially for narratives of the domestic history of the enemy countries, about which so little information had penetrated outside during the war-period. The list of writers of ex-enemy nationality, and of the articles contributed by them, shows that a considerable section of the contents, including the military history of the war itself (to which British, American, French, Italian, Belgian, German, and Austro-Hungarian soldiers have contributed), is derived from such sources; and this fact alone gives these Volumes a special interest. Consistently with this policy, the Editor has encountered only very rare disappointments in carrying out his plan of obtaining the best contributors available from all foreign countries, including Germany and Austria, in order to provide the most authoritative information on their own affairs according to their own respective standpoints. In this connexion it will be noted that, for the first time in the history of the Britannica, the article on Japan is contributed by a Japanese. The Editor is glad here to acknowledge the help of the distinguished historian, Prof. A. F. Pribram, of Vienna, in organizing, with the collaboration of Dr. Redlich, the eminent Austrian jurist, the whole series of articles dealing with Austro-Hungarian subjects. He had also the valuable assistance of Mr. George Saunders, formerly The Times correspondent in Berlin, in obtaining the cooperation of German contributors and in supervising the translation and editing of their articles; while Mr. George Adam, The Times correspondent in Paris during 1913-9, performed the same function in respect of France. In the case of Russia, the Editor was fortunately able to rely on the great authority of Sir Paul Vinogradoff. The Editor's thanks for useful advice
and assistance with regard to the articles on other foreign countries are due to President Masaryk (Czechoslovakia), Prof. H. Pirenne, Rector of Ghent University (Belgium), Prof. L. V. Birck of Copenhagen (Denmark), Mons. M. Beza, of the Rumanian Legation in London (Rumania), Mons. D. Caclamanos, the Greek Minister in London (Greece), Mons. H. N. Bronner, of the Netherlands Legation in London (Holland), Baron Alström, the Swedish Chargé d’Affaires in London (Sweden), and Mons. Erik Colbran, of the League of Nations.

So many individuals have, in one way or another, smoothed the Editor’s path, either by suggesting the best-qualified contributors or by giving helpful advice on the subject-matter of articles, that he can only make a rather arbitrary selection here in naming some of the more conspicuous. Practically every national Government, either directly or through its accredited representatives, has aided his attempt to give international authority to the New Volumes, by encouraging the use of its own sources of information; and British official coöperation, as also American, has been generously sanctioned and utilized. By the courtesy of the Naval Intelligence Department of the British Admiralty, the editorial staff had access to all the historical materials it had collected from various parts of the world for secret service during the war, including the handbooks of statistical and general information which had been privately printed by the Government for the use of British officers and political agents while the war was still in progress, and which were only partially “released” for publication afterwards. In this connexion acknowledgment may be made here, once for all, of the permission accorded by the Geographical Section of the British War Office (supplemented by that of the Controller of H.M. Stationery Office), and by the French Service Géographique de l’Armée, to reproduce British and French staff-maps, and also by the Librairie Militaire Berger-Lerrault, of Paris, to reproduce some of their maps of the battle areas. In different specialist spheres, the following acted as technical consultants: on Biology and Zoology, Dr. Chalmers Mitchell, secretary of the Zoological Society of London; on Botany, Prof. F. W. Keeble, of Oxford University; on Mathematics, Prof. G. H. Hardy, of Oxford University; on Aeronautics, Lt.-Col. Mervyn O’Gorman; on Medicine and Surgery, Dr. R. McNair Wilson; on Civil Engineering generally, Mr. H. M. Ross, editor of the Times Engineering Supplement; on Electrical Science and Engineering, Prof. J. A. Fleming, of University College, London. Each of the above was responsible for suggesting contributors on the subjects named, and assisted in coördinating their contributions. On military matters Maj. C. F. Atkinson acted for the Editor in obtaining the coöperation of a large number of expert advisers, at home and abroad, and he was responsible for organizing all the articles dealing with military history and equipment. On naval affairs useful advice was given by Rear-Adml. Sir W. Reginald Hall, M.P., and Rear-Adml. H. W. Richmond. Mr. Humbert Wolfe, of the British Ministry of Labour, and Mr. R. Page Arnot, of the unofficial Labour Research Department (the intelligence office of the British Labour movement), assisted, from different points of view, in planning the articles dealing with Labour developments, while valuable advice was received on their economic aspects from Sir Hubert Llewellyn Smith and Mr. Sidney Webb. The Editor’s thanks are due to all these counsellors; and also to Lord Stamfordham, for material in connexion with the biographical article on King George V., to Sir Godfrey Thomas as regards that on the Prince of Wales, to Sir
EDITORIAL PREFACE

Hercules Read for suggestions as to the treatment of Archaeology, and especially to Lord Justice Sir William Younger and Lord Newton, jointly and severally, for their help in securing the undertaking, by their colleague Sir Reginald Acland, K.C., of the article on "Prisoners of War," which represents the first judicial review of the evidence officially taken by Sir William Younger's committee on that subject.

In crediting the editorial staff as a whole with a loyal fellowship which alone rendered possible, by the coöperation of its various departments, the production of the New Volumes in so short a time from their inception, the Editor-in-chief must express his warmest acknowledgment of the services of the three principal assistant-editors in London—Dr. Henry Newton Dickson, D.Sc., formerly professor of Geography at University College, Reading, and Literary Director of the Naval Intelligence Department of the Admiralty during the war; Professor Walter Alison Phillips, Lecky Professor of Modern History at Trinity College, Dublin (who was able to follow up his previous association with the Eleventh Edition, as principal assistant-editor, by devoting his vacations, and such other time as he could spare, to this work); and Mrs. W. L. Courtney (Janet E. Hogarth), who, with an efficient lieutenant in Mrs. Guy Chapman, was in charge of the work done by the ladies who formed part of the staff. Apart from a general participation in headquarters control, Dr. Dickson was especially concerned with the subject-matter of geography and statistics, and with the selection of maps and illustrations, Prof. Alison Phillips with political and constitutional history, and Mrs. Courtney with the biographical articles and those dealing with the Women's Movement, and with the making of the Index, which thus supplements the Index to the Eleventh Edition under the same guiding hand which had been responsible for the great Index to the main body of the work. As Editor's Secretary, keeping touch with all departments, Mr. Arthur Bollaert Atkins also resumed his former rôle, with an efficiency which was invaluable to the editorial organization. The New York branch of the editorial staff, under Mr. Franklin H. Hooper, as American Editor, with Mr. H. R. Haxton and Dr. G. C. Scoggin as his principal assistants, acted in concert throughout with the London office, more particularly in arranging for articles by American contributors or dealing with American affairs. The Editor-in-chief was assured beforehand of the sympathetic and experienced collaboration he enjoyed in this respect by the fact that his editorial association with Mr. F. H. Hooper for such purposes had already been continuous since the year 1900. In seeing the New Volumes finally through the press, he had the advantage of having the combined force of the British and American editorial staffs brought to bear on the critical revision of the work as a whole.

As architect both of the Eleventh Edition and of the superstructure which now converts it into the Twelfth Edition, it has been the present writer's privilege to be served by an international company of practical builders, supplying the world's best available materials and masonry; and he has been inspired by the ambition of cementing and adorning, in the completed edifice, that great movement for Anglo-American cooperation, on whose progress from strength to strength the recovery of civilization after the World War of 1914-9 must so largely depend.

Christmas 1921.

HUGH CHISHOLM.
ABBREVIATIONS USED IN THESE VOLUMES

A

A.A. = Anti-Aircraft; Army Act (British); Automobile Association.

A.A.G. = Assistant Adjutant-General.

A.B.C. = Argentina, Brazil, Chile.

Abt. = Abteilung = Detachment, sub-unit (German Army), acre or acres.

A.C. = Artillerie de Campagne, Artillerie de Corps = Field artillery, Corps artillery — followed by numeral (French).

A.C.L = Army Council Instruction (British).

A.C. of S. = Assistant Chief of Staff (U.S.A.).

A.D. = Anno Domini = In the year of our Lord (Latin); Artillerie divisionnaire = Divisional artillery (followed by numeral) (French).

Adml. = Admiral.

A.E.F. = American Expeditionary Force.

A.F. = Air Force (British).

A.F.C. = Air Force Cross (British).

A.F.E.F. = Anglo-French Expeditionary Force.

A.F.M. = Air Force Medal (British).

A.F. of L. = American Federation of Labor.

A.G. = Adjutant-General.

A.I.D. = Aircraft Inspection Department (British).

A.I.F. = Australian Imperial Force.

A.L. = Artillerie Lourde = Heavy artillery (French).

Ala. = Alabama.

A.L.A.M. = Association of Licensed Automobile Manufacturers.

A.L.—Lor. = Alace-Lorraine.

A.L.V.P. = Artillerie Lourde à Voie Férée = Heavy railway artillery (French).

A.M. = Army Medical Service.

A.M.S. = Australian and New Zealand Army Corps.

A.O.C. = Army Ordnance Corps (since 1918 R.A.O.C.).

A.O.K. = Armee Oberkommando = Supreme Army Command (Austro-Hungarian); Headquarters of an army, with numeral, e.g. A.O.K. 2 (German).

A.P. = Army Pay Corps; since 1918 R.A.P.C. (British).

A.P.D. = Army Pay Department (British).

Ariz. = Arizona.

A.S.C. = Army Service Corps; since 1918 R.A.S.C. (British).

A.S.E. = Amalgamated Society of Engineers.

A.T. = Artillerie de Tranchée = Trench artillery (French).

A.V.C. = Army Veterinary Corps; since 1918 R.A.V.C. (British).

A.V.S. = Army Veterinary Service.

ABBE, CLEVELAND (1838-1916), American meteorologist, was born in New York Dec. 3 1838. He studied astronomy under Brünnow and A. B. Gould, and spent a year at the Pulkovo Observatory, 1865-6, under Struve. He was assistant at the U.S. Naval Observatory, 1867-8, and Director of the Cincinnati Observatory, 1863-72. His success there in forecasting the weather from meteorological observations telegraphed from various points led to his being called to the U.S. Signal Service in 1871. Thereafter with Government aid he was enabled to extend the field of his forecasts and became the “Father of the Weather Bureau.” The bureau was formally established in 1871 under the Department of Agriculture, and Abbe remained its head until his death Oct. 28 1916. To his initiative is largely due the introduction of the system of standardized time.

He was the author of Report on Standard Time (1879); Report on the Solar Eclipse of July 1879 (1881); An Account of Progress in Meteorology and Allied Subjects in the Years 1879-87 (1883); Treatise on Meteorological Apparatus and Methods (1888); Preliminary Studies in Storm and Weather Prediction (1880); Recent Progress in Dynamic Meteorology (1890); The Mechanics of the Earth’s Atmosphere (3 vols. of translations, 1891-1910); The Physical Basis of Long-Range Forecasting (1902); The Progress of Science as Illustrated by the Development of Meteorology (1908); Notes on Balloons and on Waterspouts from the Voyage of La Pic&e (1914) and The Introduction of Meteorology into Courses of Instruction in Mathematics and Physics (1915).

ABBEY, EDWIN AUSTIN (1852-1911), American painter (see 1.11), died in London, Aug. 1 1911. The last years of his life were devoted to mural paintings for the Capitol at Harrisburg, Pa., his native state. He completed “The Apotheosis of Pennsylvania,” which stands behind the Speaker’s chair in the House of Representatives, also “The 24 Hours” for the ceiling of the dome; but for the Senate chamber he finished only one painting — “Von Steuben Training the American Soldiers at Valley Forge.” In 1910 there was completed under his supervision the decoration of the Peers’ corridor of the Houses of Parliament. He left bequests of his works to the Metropolitan Museum of Art in New York, to the Boston Museum of Fine Arts and to the National Gallery in London. In 1912, the Old Masters’ Exhibition of the Royal Academy, held at Burlington House, London, included over 300 works of Abbe’s loaned for this special occasion as a memorial to him.

ABBOTT, LYMAN (1835— ), American divine and author (see 1.26), continued after 1910 as editor of The Outlook, and in a less degree as a public speaker, to take an active part in the discussion of important public questions. After the outbreak of the World War he supported the cause of the Allies, and on the sinking of the “Lusitania” in 1915 urged that America break off diplomatic relations with Germany. He was the author of The Spirit of Democracy (1910); America in the Making (1911, being the Yale lectures on the responsibilities of citizenship); The Four Anchors (1911); Letters to an Unknown Friend (1915); Reminiscences (1915, containing in the preface an admirable summary of his liberal views) and The Twentieth Century Crusade (1918).

ABDUL HAMID II. (1842-1918), ex-Sultan of Turkey (see 1.35), died Feb. 10 1918. On his deposition in April 1909 he was sent to Salonika as a state prisoner, but when that town capitulated to the Greeks during the Balkan War (1912) he was brought back to Constantinople. In 1915 it was judged prudent to exile him from Turkey in Europe and he was removed to Smyrna.

ABERCROMBIE, JAMES HAMILTON, 2ND DUKE OF (1839-1913), British politician (see 1.45), who served as High Constable of Ireland at the coronation of King George V. (1911), died in London Jan. 3 1913. He was succeeded as 3rd duke by his eldest son, James Albert Edward Hamilton, born Nov. 30 1869.

ABERCROMBIE, LASCHELSE (1851— ), English poet, was born at Ashton-upon-Mersey, Chs. Jan. 9 1881, and educated at Malvern and Victoria University, Manchester, where he studied science. His first work, Interludes and Poems, appeared in 1908, and his other works include: Mary and the Bramble (1910); The Sale of St. Thomas (1911); Emblems of Love (1911); Deborah (1912); Speculative Dialogues (1913) and The Epie (1914), besides a critical study of Thomas Hardy (1912). He was in 1919 appointed lecturer in Poetry at the university of Liverpool.

ABERDEEN AND TEMAIR, JOHN CAMPBELL GORDON, 1ST MARQUESS OF (1847- ), British politician (see 1.47), retained his office as Lord-Lieutenant of Ireland until 1915. On his retirement he was created Marquess of Aberdeen and Temair, the latter title being a form of the place-name Tara, chosen for its connexion with the history of Ireland. His wife, Ishbel Maria (b. 1857)—daughter of Dudley Marjoribanks, 1st Baron Tweedmouth—who he married in 1877, took a prominent part in charitable work during her residence in Ireland, becoming president of the Irish Industries Association and other societies. She did excellent work in increasing the number of nurses and establishing committees for the improvement of sanitary conditions and combating the spread of tuberculosis in Ireland. She published in 1908 Ireland’s Crusade against Tuberculosis.

ABINGDON, WILLIAM LEPER [PILGRIM] (1850-1918), English actor, was born May 2 1859 at Towecest, Northants. He began life as a bank clerk, but soon went on the stage, first appearing at Belfast in 1881. His chief successes were in melodrama, with Wilson Barrett’s travelling companies and later at the Adelphi theatre, London, where he played in The Harbour Lights (1889) and many similar pieces. Between 1903 and 1911
he appeared often in America. In 1905 he played Monks in *Oliver Twist* at His Majesty’s theatre, London. He died in New York May 20 1918.

**ABNEY, SIR WILLIAM DE WIVELESLIE** (1843-1920), English chemist, was born at Derby July 24 1843 and educated at Rossall school, obtaining a commission in the R.E. 1861. In 1876 he became C.B., D.S.C., D.C.L. and F.R.S. and from 1893 to 1897 he was successively president of the Royal Astronomical Society and of the Physical Society. In 1890 he became assistant secretary to the Board of Education; in 1903 he was appointed advisor to the science department of the Board, and the same year became a member of the Advisory council for education to the War Office. In 1900 he was knighted and in 1904 became chairman of the Society of Arts. His contribution to science was mainly in the furtherance of photographic chemistry and especially of colour photography and colour printing (see 16.661; 21.486, 408; 531; 532: 25.637: 6.729). His publications on these subjects include *Instruction in Photography* (1876); *Colour Vision, Colour Measurement and Mixture* (1893); and *Trichromatic Theory of Colour* (1914). He also wrote *Thebes and its Five Great Temples* (1876), and, with C. D. Cunningham, *The Pioneers of the Alps* (1888). He died at Folkestone Dec. 3 1920.

**ABRUZZI, DUKE OF THE [LUIGI Amedeo]** (1872- ). Italian vice-admiral and explorer, son of Amedeo, late Duke of Aosta and sometime King of Spain, was born at Madrid Jan. 29 1872. He entered the navy as a cadet and followed a regular naval career in which he achieved great distinction; but he also became well known as an eminent traveller and mountaineer. He was the first to ascend Mt. St. Elias in Alaska (1897), and in 1899 he organized an expedition with the object of reaching the North Pole; although he himself was disabled by frostbite early in 1900 and forced to remain on his ship, the "Stella Polare," Comm. Cagni pushed on with a part of the expedition and reached the lat. of 86° 34', at that time the record of northern exploration. In 1906 he was the first to ascend Mt. Ruwenzori in East Africa, reaching the twin summits (16,800 ft.), which he named Margherita and Alexandra, and also the other chief peaks of the range; he made the first detailed map of the Ruwenzori and collected much scientific information about it. In 1909 he explored the Central Karakoram in the Himalayas and by ascending peak K2 achieved the record for height; among other scientific work the expedition completed the map of the great Baltoro glacier. During the Libyan War he commanded a naval squadron in the Adriatic and had various successful engagements with Turkish warships. During the World War he was commander-in-chief of the Italian naval forces, and showed very high qualities of seamanship, strategy and organization in the extremely difficult operations in the Adriatic. He had British and French warships under his orders. He relinquished his command in 1917 owing to disagreements with Adml. Thaon di Revel, chief of the Naval Staff, and retired from the service. Afterwards he undertook an important colonization and agricultural development scheme in Italian Somaliland. He was made a Knight of the Order of the Annunziata.

**ABYSSINIA** (see 1.8).—Since 1910 boundary commissions have delimited in part the Sudan-Abyssinia and the Italian-Abyssinian frontier. No change was made in the international status of the country between 1910 and 1921. The conquests of Menelek and Menelik II of Abbyssinia were maintained. The Spanish protectorates excepted, Abyssinia was the only country of Africa neutral throughout the World War.

**Recent History.**—From 1899, a year which marked the end of an era of conquest and civil war, the Emperor Menelek (see 18.128) had maintained internal peace and had cautiously encouraged commercial relations with Europeans. But in 1910 Menelek was stricken by a malady which incapacitated him from rule, although until his death, in Dec. 1913, and for years afterwards (e.g. in 1919), his name was invoked by the people as that of the highest authority in the country. A regency was formed in 1910, consisting of Lij Yasu—Menelek's grandson, whom he had nominated his heir in 1908—and Ras Tesammas, Lij Yasu being then only fourteen. Menelek's wife, the Empress Taitu, a princess of Tigre, opposed the regency, called to her aid the Tigran chiefs, and usurped authority. She refused to see the representatives of foreign powers and stopped the building of the railway from Jibuti (see 1.95) to the capital, Addis Ababa. After maintaining her position about a year, Taitu was overthrown by a palace revolution. She took no further part in the government and died Feb. 11 1918.

Not long after the regency was established Ras Tesammas, a capable man of moderating influence, died, April 1911. Lij Yasu then attempted to reign uncontrolled. He was strongly opposed; but with the help of his father Ras Michael, chief of the Wollo Galla, Yasu made good his authority and on Menelek's death was acknowledged negus negusti (king of kings, emperor).

At that time, the beginning of 1914, the condition of the country was not without promise. The building of the railway from Jibuti had been resumed; in 1912 it had reached the Hawash river, and was then (1914) being carried up the steep escarpment to the Abyssinian plateau. Even in its incomplete state it carried in 1913 merchandise valued at over £1,000,000. A considerable trade between the Galla provinces (western Abyssinia) and the Sudan had also developed. Both Abyssinians and Gallas showed a distinct appreciation of foreign products; it needed only good government and the provision of better means of communication to have brought about a great development of the very rich natural resources of the country. Lij Yasu, however, was a youth of depraved morals, his administration was marked by waste and tyrannical, and the result was that the south anarchy, and in the north the alienation of the Tigrians, always jealous of Shoa (Menelek's hereditary kingdom). The maintenance of a large standing army was another cause of poverty and discontent. Out of a total population, according to trustworthy estimates, of from 10,000,000 to 12,000,000, about 500,000 were in the army. (Detailed figures for 1916 gave a total of 571,000 as the strength of the Abyssinian forces.) In the Galla, Somali and Shankailla (i.e. negro) provinces these men lived largely by plunder.

Such was the situation when the World War broke out. Lij Yasu had already come very much under German and Turkish influence, the chief agent in the propaganda of the Central Powers having been Herr K. Schwemmer, consul for Austria-Hungary. (Schwemmer, owing to Italian pressure, was recalled to Vienna and left Abyssinia in Oct. 1914.) Yasu had already given offence to the Abyssinians, whose attachment to their own form of Christianity is strong, by his neglect of the observances of the national church, and in June 1914 had caused his father, Ras Michael, to be crowned negus (king) of Wollo, the only province of Abyssinia proper inhabited by Moslems (Galla language). Michael remained nominally a Christian; Yasu, at first secretly and later openly, embraced Islam, and, inspired by Turco-German policy, set himself to unite all the Moslems of the empire. He married the daughters of several Danakil and Galla chiefs, and betrothed himself to the daughter of Aba Jifar, King of Jimma, the most powerful Moslem prince in the empire. He also made political alliances with Moslems outside the Abyssinian dominions, among others with the "Mad" Mullah of Somaliland, then at war with the British. His policy was summed up as (1) Moslem as opposed to Christianity; (2) Gall as opposed to Abyssinian; (3) Turco-German as opposed to the Entente.

In April 1916 Yasu officially placed Abyssinia in religious dependence on the Sultan of Turkey as Caliph and sent to the Turkish consul-general at Harrar an Abyssinian flag bearing the crescent and a confession of faith in Islam. About this time he informed his Moslem confederates—who had been told that Germany and Austria had embraced Islam and had imposed that faith upon France—that he would lead them against the Allies as soon as a great German victory should be announced.

1 One result was raiding into the Sudan and adjacent territories by Abyssinians. These raids the central Government did not or could not prevent.
His anti-Christian, anti-Abyssinian attitude led to Yasu’s downfall. The Allied representatives at Addis Ababa, in particular the Hon. W. G. Theisger, then the British minister, did much to counteract Turco-German propaganda and, except Ras Michael, all the Abyssinian chiefs were opposed to the Emperor’s proceedings. They had the support of the Shoans as well as the men of Tigré and Gondar, and they determined to end an intolerable situation. On Sept. 27, 1916—the Feast of the Cross—by a public proclamation of the Abuna (the head of the church) Lij Yasu was declared dethroned, on the specific ground of his apostasy. His aunt, the Princess Zauditu (Judith), who had been a prisoner in the palace since Menelek’s illness in 1910, was proclaimed empress. Dejaz (general) Taffari Makonnen, a cousin of Zauditu, was appointed heir to the throne and regent with the title of Ras (prince). The new regime was at once accepted, practically unopposed, by the chiefs and people of Sho and by the imperial army (a force of 50,000 kept in the neighbourhood of the capital).

Lij Yasu was then at Harrar, a Moslem centre, arming the Somalis. On receipt of the news of his deposition he showed the weakness of his character by publicly renouncing Islam, a step which gained him no credit either with the Abyssinians or the Somalis. The garrison of Harrar (Abyssinians), sent by Yasu to oppose the Shoan troops which the new rulers had dispatched against him, joined his enemies. On Oct. 8 Yasu fled secretly from Harrar, making for the Danakil country. On the 9th Harrar was occupied by the Shoan, who killed some 4000 of the regent’s forces; the slaughter was stopped through the intervention of the British consul.

Ras Michael was made of stern stuff than his son; moreover, the Wollo Galla remained faithful to him and he was able to put some 80,000 men in the field. Wollo lies on the eastern edge of the Abyssinian plateau, with Gondar and Tigré N. and N.W. and Sho to the S. Leaving 20,000 to 30,000 men to guard his northern frontier, Ras Michael marched S., hoping to capture Addis Ababa by a rapid blow. Meantime the new government had prepared to advance N., fixing on Shamo, 40 m. N.E. of the capital, as the place of conflict. Michael, who was first in the field, had an engagement with the advanced force of the Shoans under Ras Lul Seged Oct. 17, before whom he gave way.

But on the 19th Michael surrounded and destroyed Lul Seged’s force in a furious battle in which over 12,000 men perished. Lul Seged himself was slain, but his resolute defence had delayed Michael’s advance; it gave time to the Shoans to complete their concentration. By Oct. 21 they had 60,000 men at Shamo, and a great superiority in artillery over Michael. On the 22nd Shoan cavalry under Ras Kassa1 seized a position in the rear of Michael’s army; the same day his force on the northern frontier was attacked and defeated by the Wollo horsemen (Galla). Cut off from his base, almost enveloped and with supplies running short, Michael’s only alternative to being starved into surrender was to attack. The King chose the latter course and gave battle at Shamo on Oct. 27. The fighting was desperate and the slaughter great. The Shoans were at first hard pressed but the timely arrival of Ras Kassa’s cavalry decided the issue. The Wollo army was utterly routed, Michael was taken prisoner and all his artillery captured. This ended the campaign, in which in three weeks over 60,000 lives are said to have been lost, the casualties of the Sho being over 30,000. The Vittural Harold Grealis, Minister of War, who had commanded in chief the Shoan forces, made no attempt to occupy Wollo or to pursue Lij Yasu and thus effectively pacify the country. He returned to Addis Ababa where the Empress Zauditu reviewed the victorious troops, the ceremony ending with the parade of Ras Michael, a fine-looking, dignified man of about 65, chained to the chief who had captured him.

Profiting by the inactivity of the Government, Lij Yasu gathered together the remnants of his father’s army. He managed to keep his footing in the Wollo country for the greater part of 1917, finally moving eastward into Magdala. Closely besieged by the forces of Ras Michael, the town of Magdala surrendered in Dec. 1917. Lij Yasu escaped, and later appears to have led a wandering life among the Danakil and Somalis. In Oct. 1918 he was appealing to the Turks in Arabia for help, and making attempts to raid the Jibuti railway. At the close of 1920 Yasu appeared in Tigré, apparently hoping to gain over that province, but in Jan. 1921 the regent dispatched by the Shoans defeated him.

The Government of the Empress Zauditu and Ras Taffari was pro-Allied and in the summer of 1916 missions were sent to London, Paris, Rome, Brussels and Washington to congratulate the Allies on their victory. These missions received good advice as to the necessity of an amelioration of social conditions in Abyssinia, the suppression of slavery—Menelek’s conquests had given a great impetus to the slave trade—and the development of commerce and agriculture.

Economic Conditions and Trade.—Two great hindrances to the economic development of the country have been stated—illiteracy, disturbances and lack of adequate means of communication. After the close of the World War, and with the railway from the Gulf of Aden to Addis Ababa completed, an improvement was anticipated. A Société des Chemins de fer du Bourbonnais, formed in Dec. 1918, with the approval of the Foreign Office, but owing to restriction of shipping, the fluctuations of exchange and the fall in the price of coffee, these hopes have not been fulfilled. The old-time monopoly of coffee and beeswax is broken, the chief imports are cotton goods and Maria Theresa dollars (minted at Trieste and an exact reproduction of the 1780 issue). The external trade of northern Abyssinia with the Turco-German commerce reached £4,500,000; and with Jibuti and, to a small extent, with Zeila and Berbera (British Somaliland). These were all ancient routes to the sea-coast; to the old trade routes to the Sudan by the Blue Nile has been added that by the Baro-Solot rivers. Gambia, on the Baro and 60 m. within the Abyssinian frontier, was leased to the Sudan Government in 1907, and in the Solot flood season (June-Nov.) a steamer service is maintained with Khartoum. Although the road from Khartoum to the Baro river to Gore, on the highlands, was and remained very bad, Gambia became an important transport centre. The value of its trade, £43,000 in 1910, was £60,000 in 1913 and was estimated at £70,000 in 1919. The trade in hides followed closely, the hands of Greeks, Syrians and Arabs. The agricultural and mineral wealth of the country remain as yet—if the cultivation of coffee be excepted—scarcely tapped, as its water-power unutilized.

ACHENBACH, ANDREAS (1815—1910), German painter (see V. 1.142), died in 1910.

ACHURCH, JANET [MRS. C. CHARRINGTON] (1804—1916), English novelist, was born in Manchester Jan. 17 1804. She married Charles Charrington June 8 1889. She first appeared at the Olympic theatre, London, Jan. 8, 1848, with Genevieve Ward in the farce of Betsy Baker. Two years later she joined Frank Benson’s company and played Shakespearean heroines; but her chief success was as Nora Helmer in Ibsen’s A Doll’s House, when that play was first produced in England in 1889. She appeared later in other Ibsen plays and in those of Bernard Shaw. She died at Ventnor Sept. 11 1916.

ADAM, JULIETTE (1856—1931), French writer (see I.172), whose volumes of reminiscences of distinguished contemporaries numbered seven by 1910. Subsequently appeared Impressions francaises en Russie (1912) and Chrétienné (1913), as well as various writings in pursuit of her lifelong policy of revanche, L’heure vengeresse des crimes bismarckiens (1913), Guillaume II. 1890—9 (1917), and a volume of war sketches, La vie des armées (1919).

ADAM, PAUL (1862—1920), French novelist (see I.172), published in his later years various novels, including Le Trust (1910) and Stéphanie (1913). He was active in propaganda work during the World War, and shortly before his death published Reims dévastée (1920) and Guerre. He died in Paris Jan. 7 1920.

ADAMS, HENRY (1838—1918), American historian (see I.175), died in Washington, D.C., May 27 1918. In 1910 his Letter to...
ADAMS—ADEN

American Teachers of History appeared, and in 1911 his Life of George Cabot Lodge. In 1913 his Mont Saint Michel and Chartres (privately printed in 1904) was published by authority of the American Institute of Architects, a scholarly interpretation of the architecture and literature of the mediaeval Church. In 1918 his autobiographical The Education of Henry Adams (privately printed in 1906) was issued for the public. No book of its decade evoked more discussion in America. In 1919 The Degeneration of the Democratic Dogma (consisting of several essays previously published together with one hitherto unpublished) was issued, with an introduction by his brother, Brooks Adams. His brother, CHARLES FRANCIS ADAMS (see 1.175), died in Washington, D.C., March 20, 1915. In 1911 he published Studies Military and Diplomatic, 1775–1885, and in 1913 Trans-Atlantic Historical Solidarity (lectures delivered at Oxford).

In 1916 Worthington C. Ford edited Charles Francis Adams, an Autobiography, from papers deposited in 1913 with the Massachusetts Historical Society. See also the same editor's A Cycle of Adams Letters, 1861–1865 (1920).

ADAMS, MAUDE (1872— ), American actress, was born in Salt Lake City, Utah, Nov. 17, 1872. Her family name was Kiskadden, but she adopted the maiden name of Adams, of her mother, an actress. She early played child parts, and at the age of 16 went to New York. From her appearance in Hoyt's A Midnight Bell, in 1889, her popularity grew steadily. In 1897 she was first starred by Charles Frohman as Lady Babbie in The Little Minister; and in many of Barrie's other plays she won applause. She introduced Rostand to the American stage, taking the title-role in La Aiglon (1901), and in Chantecler (1911). Other plays in her repertory were Romeo and Juliet (1900); The Prettiest Sister of Joel (1903); The Jest's (1908) and As You Like It (1910).

ADAMS, WILLIAM (1862— ), British Labour politician, was born at Halbethe, Fife, April 2, 1862. When very young he began to work in the pits, and for many years led the life of a miner. In 1900 he became assistant secretary of the Fife and Kinross Miners' Association, and in 1908 its general secretary. He stood for Parliament unsuccessfully in Jan., 1910, but in Dec. was elected for West Fife. On the reorganization of the Labour party in 1917, Mr. Adamson succeeded Mr. Arthur Henderson as its chairman, and in 1918 he was sworn of the Privy Council. In 1919 the Labour party, as the second strongest combination in the House of Commons, decided to assume the position of the official Opposition, and Mr. Adamson became its leader, taking his seat on the front Opposition bench. As an Opposition leader he also congratulated the Speaker upon his re-election. He took part in the debate on the King's speech, pointing out the views of the Labour party on the industrial situation. Mr. Adamson took a prominent part in the various trade-union discussions in 1919, 1920 and 1921, particularly in the numerous debates on the coal industry in these years.

ADAMS, JANE (1860— ), American sociologist (see 3.183), published Twenty Years at Hull House (1910), with much autobiographical comment; A New Conscience and an Ancient Evil (1911) and The Long Road of Women's Memory (1916). She did much to promote the cause of woman suffrage, and in 1912 was an active worker in behalf of the short-lived National Progressive party. After the outbreak of the World War in Europe she attended the International Congress of Women held at The Hague in 1915, and was elected president. She was also appointed chairman of the International Committee of Women for Permanent Peace. She was an avowed pacifist after America had entered the World War.

ADDISON, CHRISTOPHER (1869— ), English politician and medical practitioner, born June 10, 1860, at Hogsthorpe, Lincolnshire, was educated at Trinity College, Harrogate, and received his medical training at St. Bartholomew's hospital. He graduated at London University, taking the M.B. (Honours in For. Med.) and the B.S. in 1892, and the M.D. in 1893. He was elected F.R.C.S. in 1895. He became lecturer in Anatomy both at his own hospital and at Charing Cross hospital; professor of Anatomy at University College, Sheffield; and Hunterian professor at the Royal College of Surgeons in 1901. Besides the private practice of his profession, he contributed largely to medical knowledge by the publication of several books, mainly on the anatomy of the pancreas and the abdominal viscera, by papers in the Proceedings of the Royal Society and in professional journals, and by editing for a time the Quarterly Medical Journal. He took, moreover, a leading part in medical education in London University. In 1910 he entered Parliament as Liberal member for Hoxton. He immediately became active in the House. In conjunction with Sir George Newman he was mainly instrumental in securing the medical treatment of school children and State provision for medical research; and he was one of the few doctors of distinction who supported Mr. Lloyd George in his struggle with the profession over the Insurance Act (1912). The valuable support he then gave to Mr. Lloyd George in reconciling the doctors to his proposals created a firm bond between him and the future Prime Minister. When in 1914 Mr. Charles Trevelyan, on the outbreak of war, resigned the Parliamentary Secretaryship of the Board of Education, Dr. Addison was appointed in his place. But his principal work during the war was effected at the Ministry of Munitions, where he was appointed Secretary. At the outbreak of war, the Ministry was formed and the Secretaryship was given to Mr. Arthur Balfour. In 1915, at the end of his term at the Ministry of Munitions, he returned to the War Office as Secretary of State for War. He was elevated to the peerage as Baronet, of St. Stephen's, Twickenham, in 1917. In the same year he was raised to the Lordship of the Manor of Hoxton, and in 1918 was also created Viscount Addison, of Hoxton in the County of Middlesex. In 1919 he was created a Knight of the Thistle. In 1921 he was made Secretary of State for Scotland. He is also a bencher of St. John's College, Oxford, of which he was made an Honorary Fellow in 1915. He has served as a member of the educational and scientific committees of the League of Nations, and is a member of the Board of Trade. He has been actively identified with the Imperial Defence League and Imperial Defence Association. He is a TRINITY COLLEGE, Cambridge, M.A. (1911), and was a fellow of Trinity College, Cambridge, for five years. He is a Fellow of the American Philosophical Society, and a member of the Royal Society of Literature. He was created an honorary LL.D. by the University of Dublin, and an honorary LL.D. by the University of Oxford. He was also a Fellow of the Royal Society of Literature, and a member of the Royal Society of Literature. He was created an honorary LL.D. by the University of Dublin, and an honorary LL.D. by the University of Oxford. He was also a Fellow of the Royal Society of Literature, and a member of the Royal Society of Literature. He was created an honorary LL.D. by the University of Dublin, and an honorary LL.D. by the University of Oxford. He was also a Fellow of the Royal Society of Literature, and a member of the Royal Society of Literature.
On March 1, 1921, the administration of Aden was transferred from the Constantinople Conference, which exercised a political influence, in varying degrees, over the confederations of tribes inhabiting the interior as far as the Yemen frontier and over certain tribes of the Hadhramaut. The revenue in 1914-5 amounted to £7,122,000 from the Aden Port Trust Fund (£34,000), Aden Settlement Fund (£28,000), Local Supply Bills (£257,000), imperial and municipal revenue. The total amount of Debts, interest, and income tax. The expenditure in the same year was £556,000.

The value of the total trade (including specie) amounted to £5,126,000 (1913-4), and had increased to £10,045,000 in 1918-9 and £17,410,000 in 1919-20. The amount of £7,122,000 represented exports and £5,171,000 imports. A very large proportion represents simple transhipment; but Aden is also the centre of the exporting and importing business of the Red Sea commercial region, and Aden and Aden-Portuguese supplies of Abyssinia and British and French Somailand. The principal articles of import in 1919-20 were: cotton piece-goods and yarn £2,180,000, hides and skins £2,123,000, coffee £56,000, grain and pulse £259,000, tobacco £213,000 and salt £51,000. Local products, including live wood, live animals, ghi, dates, honey, wax, gums and sesame oil, to the value of about £125,000, were exported in 1919-20. 1,005 steam vessels of aggregate tonnage 2,736,391 and sailing craft of tonnage 3,853,546; the year 1918-19 was free except for a small duty on alcoholic liquors and intoxicating drugs. Licenses are required for the importation of petroleum and spirits and for the manufacture of cigarettes.

The water supply, formerly very uncertain and unsatisfactory, is mainly from reservoirs and from condensation. The reservoirs have a storage capacity of 8,000,000 gal. but the most effective supply is obtained by condensation of sea water. Six condensers yield 52,000 gal. daily.

Aden produces no foodstuffs. The only local industries are the preparation of salt (Italian and Indian concessions, with an output of 124,000 tons in 1916-7); the unhusking of Arabian coffee berries and the making of cigarettes from tobacco imported from Egypt. The main trade routes are:—to San'a, via Lahej, 227 m.; to Ta'izz and Hodeida, via Ta'izz, 299 m.; and to Makalla, via Nisab, 413 m.

During the World War, Turkey brought pressure to bear on certain of the tribes of the Aden Protectorate (see ARABIA) and in July 1915 a barracks was raised in the Aden area. Aden and Lahej, the 'Abdali capital (21 m. N.). A small British force sent to assist in its defence proved altogether inadequate and had to retreat to Aden. The Turks occupied Sheikh 'Othman, but were unable to threaten Aden itself. The local Sultan was killed. On July 20 of the same year reinforced: Aden troops surprised the Turks at Sheikh 'Othman, inflicted on them considerable loss and they retired to Lahej of October, and lost their cavalry when small arms with enemy reconnoitring parties in which the latter were driven off. In Jan. 1916, owing to the Turks again dispatching troops to coerce the tribes in the east of the Protectorate, a detachment of troops was sent out to Lahej and in December the enemy were drawn. The British force was reinforced and the enemy withdrew. The southern districts, especially those of Lahej, were made a special force. It was formed, with the exception of dates, all from the different classes. The company's formation was of the order of the day: it was the time of the National party, and the best methods seemed to him to be those of public propaganda and open political warfare. The united Labour party (Arbeiterpartei) was to keep the socialistic ideal constantly in view, but was not to despise small gains. By his sound judgment, and his exceedingly clever handling of men, he succeeded, in spite of difficulties within and without the party, in reaching the first stage in the path he marked out by carrying the whole party with him, in the last days of the year 1888, on the basis of a carefully weighed programme at the party meeting held at Hainfeld, Lower Austria. He was able to appear in July 1890 at the first congress of the Second International (of which he was from that time an official) as the representative of the united Austrian party; and the first May Day celebration (1890), the first of those imposing demonstrations by which he sought to give a striking proof of the will and the power of the working classes, showed that a new epoch had dawned for Austrian Social Democracy. Adler, who was repeatedly involved in legal proceedings and condemned to terms of several months' imprisonment for political offences, was from that time the acknowledged leader of the party.

In consequence of the ever-increasing extension of its industrial and political organisation, in which Adler took an energetic part, the party obtained an increasing influence in public life, which was further increased by the division of the bourgeois parties on the nationality question. Adler understood how to make the best of these conditions. He regarded it as his first task to secure for the workmen's representation in Parliament. After the three years' struggle for electoral reform (1893-6), which followed the proposals for the modification of the franchise put forward by the prime minister, Count Taaffe, some measure of electoral reform was secured. But it was insufficient, and it was only when the government had decided that an allegedchange of the franchise was the sole means by which the monarchy could be protected against the centrifugal forces of nationality, that Adler was able to use the impression made by the confusions in Hungary and the Russian revolution of 1905 to interpose with all his weight and help to secure the triumph of universal and equal suffrage (1907).

The Social Democratic party increased their representation from 11 deputies to 87. Adler himself entered the Diet of Lower Austria in 1902, and in 1905 was elected to the Reichsrat, where until his death he played an important part as chairman of the committee of the Social Democratic party and of the Social Democratic Deputies' Club, taking part in all important debates.

New dangers, due to the nature of the Austrian State with its rival nationalities, more than once threatened the unity of the
part. Adler had always been a Pan-German, but regarded the disruption of Austria and the union of German Austria with Germany as a distant goal which had no place in the practical politics of the moment. He aimed therefore at establishing a friendly relation between the nations on the basis of democracy. When the Austrian Germans were threatened by the language ordinance of Count Badeni, and Parliament itself by a coup d'etat, Adler made an alliance with the German parties, rallied the working classes, and overthrew the Polish prime minister (1897). At the party congresses, Adler tried to accommodate the conflicting national standpoints on the basis of the principles laid down in the Brünn programme (equal rights and national autonomy). But the unified organization of the trade unions and the union of the Social Democratic parties were destroyed in consequence of these differences, more especially by the inscrutability of the Czechs. No general party congress of the different Austrian nationalities has taken place since 1905.

In the congresses and in the secretariat of the International Adler, with Jaures and Bebel, played the most prominent part, whether as leader, adviser, or mediator. He took part in the great peace demonstration of the International at Basle, and in the new secretariat in London and the immediate outbreak of the World War. In spite of bad health, which for many years in succession had compelled him to spend much time on the Riviera and at Nauheim, he travelled in the spring of 1917, immediately after the trial of his son Friedrich, to Stockholm to the proposed Socialist congress. After the collapse of Austria in 1918, at the constituent session of the provisional German-Austrian National Assembly, which was formed by the meeting of all the German deputies, he read the declaration of the Social Democrats, in which they expressed their willingness, in association with the other German-Austrian parties, to build the new State on the basis of democracy and the self-determination of their own and other nationalities, without prejudice to a possible association with the German Empire.

In his opening words Adler said: “You will permit an old man to say that at last we see the accomplishment of what we have longed for since our youth.” He did not long survive that day. He held for a few days the office of Foreign Minister, entrusted to him by the new State Council (Staatsrat), but in spite of his iron determination he was not able to bear the strain. He broke down on Nov. 11 and died on the 12th, 1918, the day on which the State Council had decided to proclaim Germany a democratic republic and an integral part of the German Reich.

His works include articles scattered in various newspapers, in the Neue Zeits, Kampf, Deutsche Zeitung; in addition to: Arbeiterzeitung: pamphlets, among which are: Die Fabrikationskondition insbesondere in England und der Schweiz (1884); Die Arbeiterkongress und die Arbeiter (1886); Das allgemeine, gleiche und direkte Wahlrecht und das Wahlrecht in Oesterreich; Alkoholismus und Gewerkschaft (many editions). See also Die Gleichheit vor dem Ausnahmegesetz (1896); Schwurgerichtsprozess gegen Docteur Viktor Adler wegen Verbrechens der Störung der öffentlichen Ruhe (1894).

His son, Friedrich Adler (1870–1912), Austrian politician, was born at Vienna July 9, 1870. He was educated at the Realgymnasium in Vienna, and studied philosophy at the university of Zurich. He was privat-docent in the University of Vienna in physics at the universities of Zurich from 1897 to 1911, editor of the Social Democratic daily Volksrecht from 1910 to 1911, and from 1911 to 1916 secretary of the Austrian Social Democratic party and editor of the monthly Kampf. During the World War he was in sympathy with the conclusions reached at the conferences of the Socialists of the Left at Zimmerwald and Kienthal. In despair over the break-up of the International, he shot (Oct. 21, 1916) the Austrian prime minister, Count Sturig, in the expectation that the deed would be a signal for the rising of the proletarian against the war. After a speech in his own defence which aroused much attention he was on May 10, 1917, condemned by a special tribunal to death, a sentence commuted to 18 years' imprisonment. During the chaos of the autumn of 1918 he was amnestied (Nov. 1). In 1919 he was elected to the National Assembly, and became vice-president of the committee of the Social Democratic party and of the Union of the Social Democratic deputies. As president of the Austrian National Workmen's Council and of the Vienna District Workmen's Council he exercised great influence in the party. On his initiative was founded the International Labour Association of Socialist Parties, of which the first meeting was held in Vienna in Feb. 1921. He made the opening statement, and became secretary of the Association.

His works are: Die Erneuerung der Internationale (1918); Ernst Mach's Ueberwindung des mechanischen Materialismus (1918); Die Ortszeit, Systemzeit, Zonenzeit und das ausgezeichnete Bezugssystem der Electrodymanik, eine Untersuchung über die Lorentzstriche und die Einstein'sche Kinematik (1920). See also Friedrich Adler vor dem Ausnahmegesetz (1919).

ADMIRALTY ADMINISTRATION (see I. 195).—The history of the British Admiralty during the World War of 1914–8 is the history of the evolution of the naval staff and of a great expansion of the technical and administrative departments. All departments expanded during the war, but the evolution of the naval staff was more than mere expansion, for it represented the adoption of definite principles of staff work which were intended to prevent those responsible for the conduct of naval operations being crushed under a load of administrative business.

This was, indeed, no new trouble. It had been experienced at home, as well as abroad, and it had all along been commented on strongly. “We are every day,” wrote the former to Middleton in 1770, “plagued and puzzled with minutiae from morning to night whilst essentials are neglected.”

“It cannot be right,” wrote Tryon in 1809, “that the Commander-in-Chief should find himself devoting his time to-coaling and watering, provisioning, storing and repairing.”

They were seeking after a solution of the difficulty which lay in a clear distinction between fighting and supply, between the use of the weapon, and its supply and maintenance in an efficient state. This principle had been introduced into the British army by Lord Hardinge, and its application for it was made essential. It is a principle vital to war, for on the outbreak of war the whole rhythm of work changes. Work expands tenfold in extent and an hundredfold in urgency, and without some clear distinction of this sort it is impossible to give to the conduct of operations the attention it deserves.

The principle was not to be found in the British Admiralty at the beginning of the war. The First Sea Lord was just as interested in the design of ships as in operations, and the War Staff lacked some of the most important elements of staff work. The important distinction between fighting and supply was not to be found; the Chief of the War Staff had no seat on the Board, and the methods of conducting the work of a large staff had not been studied. Up to 1909 the Intelligence Department had to some extent filled the place of a staff. It had gradually grown from the Foreign Intelligence Branch or Committee instituted in 1883, and had developed into the Naval Intelligence Department, consisting of four divisions—foreign, trade, mobilization and war—of which the two latter were evidently tentative efforts towards an Operations Division. In Sept. 1909 it split into two separate departments, intelligence and mobilization, of which the latter was clearly the beginning of an Operations Department. It was not by its application for it soon became immersed in the task of manning and mobilization, which belongs wholly to the sphere of supply. The Intelligence Department sank more and more into the position of a mere handmaid for the collection of data and translations from the foreign press. Its development was hampered by the intense suspicion with which most flag officers regarded anything that seemed to trespass on their prerogative of command. The idea of a staff was held in great disfavour. The word was anathema at the Admiralty and not allowed to be used in War College publications, and it is no secret that the most distinguished flag officers were opposed to the institution of a staff in 1912.

The naval staff really dates from the Memorandum of Jan. 1912 issued by Mr. Churchill, after the breakdown of the old system at the Agadir crisis, but it had not had sufficient time to develop before the World War broke on it and broke it up. It consisted of three small divisions—operations, intelligence
and mobilization. Its deficiencies may be briefly summarized: Firstly, the Chief of the War Staff was not a member of the Board, and could not act with Board authority; his function was merely advisory. Secondly, there was a great insufficiency of trained staff officers, and the War Staff proved quite inadequate in numbers and training to deal with the business of war. Thirdly, the principles of staff work had not been studied, and the vital distinction between fighting and supply was not to be found. Fourthly, the system found little support either at Whitehall or in the fleet at sea. There was no clear conception of conducting the work of a staff, or of grafting it on to the business system of the Admiralty. On the first day of war a number of sections were bundled into one big room in order to be as close as possible to one another to the serious dislocation of their work. The Operations Division was divided on the basis of types of ships rather than of areas. It soon became absorbed in current work, and had no time for the examination of large plans, which might require three months' work merely to reduce to terms of time and supply. The enormous importance to a staff of an operations chart clearly and continuously visualizing the situation was not appreciated. An operations chart was started, but gradually over-centralization and the obsession of secrecy came down on it like a thick fog and turned it into a fiasco. The movements of transports were kept a profound secret, and news of them was withheld. Secret telegrams (pink telegrams) were started about Nov. 1914 but were not passed to the War Room to be plotted on the chart, which degenerated into a patchy report of reports around the fleet. Up to 1917 there was no chart to which a staff officer could go and see at a glance the actual situation at the moment in any and every area.

The work which ought to have been done by the staff was done by a small group of two or three flag officers acting in an advisory capacity to the Board, and the system seemed to be designed for the special purpose of making it as difficult as possible to obtain information. The Intelligence Division was expanding and developing under Capt. (later Adml. Sir) William R. Hall, but its sections had to fight hard to obtain information as to British movements. The flag officers worked for the Board, not for the staff, and no one quite knew what they did or where they did it.

Let us consider the constitution of the Admiralty Board when the war broke out. Under a patent of Dec. 1 1913 it consisted of the First Lord, Mr. Winston Spencer Churchill (since Oct. 24 1911), Adml. Prince Louis of Battenberg (3rd S.L., since Dec. 9 1912), Vice-Adml. Sir Frederick Hamilton (2nd S.L.), who had succeeded Vice-Adml. Sir John Jellicoe (July 30 1914), Rear-Adml. Sir Archibald H. Moore (3rd S.L., since May 29 1913), Capt. C. H. Smith D.S.O. (4th S.L., since Jan. 1 1913), Mr. George Lambert, M.P. (Civil Lord, since Dec. 27 1905), Sir Francis J. S. Hopwood (Parliamentary and Financial Secretary since Jan. 78 1912, later created Lord Southborough), with Sir Graham Greene as Permanent Secretary. Its business was governed by an Order in Council of Aug. 10 1904, which made the First Lord responsible to His Majesty and Parliament for all the business of the Admiralty, and from time to time with his sanction various memoranda were issued regulating the distribution of business. The distribution of business had remained materially the same for many years, though the memorandum actually in force at the outbreak of war was dated Jan. 1914.

The First Sea Lord was responsible for advising on preparations for war, for the fighting and sea-going efficiency of the fleet, and for the superintendence of the War Staff. The 2nd Sea Lord was responsible for personnel; the 3rd Sea Lord for materials; the 4th Sea Lord for transport and stores, full and half pay, salvage and collisions. No one was specially responsible for the conduct of all operations of war, and though this presumably rested with the Chief of the War Staff he was not a member of the Board, and at least two flag officers senior to him were acting in an advisory capacity to the Board. The First Sea Lord was responsible for the "fighting efficiency of the fleet," a phrase covering an immense technical scope and opening out an endless vista of all sorts of considerations.

It is interesting to observe that the distinction between fighting and supply, which lies at the basis of modern staff organization, existed in a simpler form in the organization of Henry VIII., which continued in force in the British navy down to 1832. In this organization the Lord High Admiral or Commissioners of the Admiralty exercised the function of general control and was responsible for the conduct of a war, while the actual supply services were performed by four principal officers, namely, the Treasurer, Comptroller, Surveyor and Clerk of the Acts, responsible respectively for finance, supervision of accounts, building and upkeep of ships, and record of business. These officials came to be known as the Navy Board, and the organization of the Admiralty from 1546 to 1832 was roughly as follows:

<table>
<thead>
<tr>
<th>Appointments</th>
<th>Supply</th>
<th>Policy</th>
<th>Operations and Movements</th>
</tr>
</thead>
<tbody>
<tr>
<td>Officers</td>
<td>Navy Board</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Lord High Admiral or Commissioners for executing his office</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Pay, Stores (other than Ordnance and Victualling) Manning, Shipbuilding, Dockyards Sick and Hurt Board

Here the work of supply is kept distinct from the business of fighting, and it was under this dual organization, in which the Navy Board was responsible for the multifarious requirements of war, that the earlier wars were fought. Unfortunately, the supply system was often bad and insufficient and corrupt, though its defects were due just as much to limitations of the time as to the system. The work was not closely coordinated, with the result that Sir James Graham in 1832 merged the functions of the Navy Board and the Admiralty, an amalgamation which was regarded as a master stroke at the time and had distinct advantages, but unfortunately neglected to retain the principle of distinction between the Admiralty and supply, with the result that it was not the Admiralty that swallowed the Navy Board but the Navy Board that swallowed the Admiralty. The general constitution of the Board, though it varied from time to time, may be represented as follows:

<table>
<thead>
<tr>
<th>Board of Admiralty</th>
</tr>
</thead>
<tbody>
<tr>
<td>First Lord</td>
</tr>
<tr>
<td>Preparations for war, fighting efficiency</td>
</tr>
<tr>
<td>2nd Sea Lord: Personnel</td>
</tr>
<tr>
<td>3rd Sea Lord: Material</td>
</tr>
<tr>
<td>4th Sea Lord: Transport and Stores</td>
</tr>
<tr>
<td>Civil Lord: Works</td>
</tr>
<tr>
<td>Permanent Secretary Financial Secretary</td>
</tr>
</tbody>
</table>

Note.—According to the Order in Council of Aug. 1904 the First Lord is practically supreme as being responsible to the King and Parliament, but according to the terms of the Patent "two or any more of you" can exercise the office.

In 1860 commenced that vast multiplication and development of technical crafts and branches which began with the steam engine (the last sailing ship of the time, the Ganges, was paid off in 1861), and exercised an enormous influence on the navy and naval thought. The result in conjunction with Sir James Graham's amalgamation was inevitable. Between 1860 and 1900 the study of strategy and of staff work, which is the business side of war, was practically ignored. All the talent and brains of the navy flowed to the great technical schools. The whole trend of thought for forty years was exclusively technical. It was supposed that war and the conduct of war was quite a simple matter for any flag officer and needed no study. This simple creed received a rude shock at the time of the Afghan crisis when the Admiralty plans for war were torn to shreds by the General Staff. A War Staff was then instituted. But the War Staff had hardly been weaned and had not yet found its
feet when the World War broke out. It laboured under a further handicap: practically all senior officers were opposed to it. They were wedded to centralization. Centralization had become engrained in their bones from boyhood, and their whole outlook was necessarily opposed to a staff. The deficiencies of the system could be seen in the conduct of the Dardanelles campaign. It is clear that there was no machinery for the intensive investigation of a big strategical question. The First Lord was impressed with an exaggerated estimate of the Queen Elizabeth's guns, and the War Staff could neither supply a sufficiently trenchant criticism of the project nor could they grip the problem and transform it into a workable proposition by segregating a force and training it as the Zeebrugge force was afterwards trained.

Enough has been said to show that the war staff lacked the staff spirit, and a knowledge of the principles of staff organization and of the conduct of staff work. One bright spot, however, shone in the May 1917, when the term “War Staff” was altered to “Naval Staff” and the office of Chief of the Naval Staff was merged in the First Sea Lord (Admiral Jellicoe), while a Deputy Chief of the Naval Staff (Vice-Admiral Oliver) and an Assistant Chief (Rear-Admiral Duff) were appointed with seats on the Board. This gave the naval staff direct representation on the Board, and the presence of three members ensured the necessary authority to carry through any operation of war. The D.C.N.S. directed all operations and movements of the fleet, while the A.C.N.S. was responsible for mercantile movements and anti-submarine operations.

Sir Eric Geddes gave an immense impetus to the system, which was forced upon the Government by the exigencies of war, and in its main outlines was merely the system of Moltke, Lord Haldane, and every modern army, adapted to naval needs. These can be briefly summarized as follows. The work of a staff follows three lines of practical cleavage: (a) operations (or direction), (b) administration, and (c) technical. Operations (or direction) enshrines the main purpose of a business; administration is responsible for its maintenance and equipment an efficient state; technical control deals with the scientific aspect of applied sciences associated with the business. Finance and the Secretariat interpenetrate the whole. Operations (or direction) is the premier function, and splits into two main divisions, operations (minor) and intelligence. It is the special task of operations to appreciate the situation continuously, to assist the Command in the consideration of requirements and with the preparation and conduct of operations, and to convert the intentions, policy and decisions of the Command into orders and instructions. It is its business to visualize the situation continuously on an operations chart and to furnish all branches and technical services with timely information of all requirements. The function of intelligence is to collect, sift and distribute information of the enemy, and by the cumulative intelligence arising out of its work to help operations to appreciate the situation. Administration and technical comprise all the great services of supply and technical work, including personnel, pay, victualing, stores, transport, and the crafts of hydrography and surveying, navigation, marine engineering, naval construction, gunnery, torpedoes, mine-laying, mine-sweeping and signals. Each service is responsible for its internal efficiency, and the Chief of the Staff is responsible for the coordination of all, while to assist him in this a training and staff division is required which acts as the trustee of staff principle and organization, and is also responsible for staff training, principles of training, staff history and manuals of war. No one of the three great branches is more important than another. Like the brain, heart and lungs, all are complementary to each other. If there are no ships there can be no operations; if the operations are badly conducted, the best ships will be useless; a new technical invention may revolutionize operations, and the whole service must rest on a basis of good discipline and sound financial administration.

The first step towards these principles was really taken in May 1917, when the term "War Staff" was altered to "Naval Staff" and the office of Chief of the Naval Staff was merged in the First Sea Lord (Admiral Jellicoe), while a Deputy Chief of the Naval Staff (Vice-Admiral Oliver) and an Assistant Chief (Rear-Admiral Duff) were appointed with seats on the Board. This gave the naval staff direct representation on the Board, and the presence of three members ensured the necessary authority to carry through any operation of war. The D.C.N.S. directed all operations and movements of the fleet, while the A.C.N.S. was responsible for mercantile movements and anti-submarine operations.

The office of Controller was revived, and Sir Eric Geddes appointed to fill it, with the rank of Honourary Vice-Admiral, all questions of supply being thus practically merged in his hands; but he had barely filled the office two months when he took Sir Edward Carson's place as First Lord July 20 1917. On Sept. 6 1917 a Deputy First Sea Lord, Sir Rosslyn Wemyss, was added to the Board to control operations abroad and questions of foreign policy. Sir Oswyn Murray too had succeeded Sir Graham Greene as Permanent Secretary in Aug. 1917.

In Oct. 1917 the development of the staff was carried one step further by the formation on Oct. 19 of two Committees of the Board—the Operations Committee and the Maintenance Committee. The First Lord was chairman of both, and the former consisted of the First Sea Lord and C.N.S., the Deputy 1st S.L., D.C.N.S., A.C.N.S., and 5th Sea Lord. The latter consisted of the Deputy 1st S.L. (representing the operations committee), 2nd S.L. (personnel), 3rd S.L. (material), 4th S.L. (transport and stores), Civil Lord, Controller and Financial Secretary.

The direction of operations was finally handed over to the C.N.S. by an order in Council of Oct. 1917, under which he became responsible for the issue of orders affecting war operations to the fleet. It empowered such orders to be issued in his own name as C.N.S., and not as previously by the secretary in the name of the Board.

These measures were accompanied by the institution of further divisions of the staff, including a plans division, and by Oct. 1917 the Board and naval staff had assumed the following form:

<table>

Mercantile Movements

Oct. 1 1917 (Capt. Fred Whitehead)

A.C.N.S. (R.A. Duff)

One of the most important divisions of the naval staff was the mercantile movements division, which had been started as a convoy section, under the management of Paymaster Capt. H. W. Manisty. It was here in May 1917 that an operations chart came into use for the direction of convoys, on which the movements of submarines derived from wireless directionals and other reports were plotted, day and night. Operations divisions, troubled like Martha over many things, had never been able to deal in big plans, and this work was undertaken by the plans division which drew up plans for the mining of the Bight, the Great Northern Barrage (in conjunction with the U.S. navy), the Dover Barrage, the Otranto Barrage and numerous smaller operations.

The ease with which the distinction between operations and administration can be applied is illustrated in the submarine and auxiliary patrol services. In both these services the administrative work (such as regulations, conditions of entry, stores, personnel) was dealt with by a centre which had very little or nothing whatever to do with operations (Commodore S in the one case and the Auxiliary Patrol Office in the other), and the system worked very successfully from first to last. The reorganization of staff work was not limited to the Admiralty. It extended to every command, and in April 1918 the First Lord and Rear-Adml. Sir W. R. Hall proceeded to Malta and made arrangements for the entire reorganization of the C.-in-C.'s staff, leading to a great reduction in shipping losses in the Mediterranean.

With the advent of peace the naval staff was greatly reduced, and some divisions naturally disappeared. A change of some importance has taken place in the function of the A.C.N.S., who has become responsible for all staff questions relating to technical branches and crafts such as gunnery, torpedoes and mining. Gunnerly and torpedo divisions have been introduced into the staff to deal with questions of the tactical use of these weapons and the training of personnel. The plea for this lies in the close connexion between the use of the weapon and operations. There can be no doubt that training and the tactical aspects of weapons constitute a sphere common to the naval staff, the great technical departments and the fleet, but though they certainly require to be in close touch with the naval staff it still remains a moot point whether all technical crafts with the training that belongs to them should not be segregated from the naval staff.

The distribution of the naval staff in 1921 was as follows:

1st S.L. and C.N.S.

D.C.N.S.

Intelligence

Operations

Plans

Local Defence

Trade

Training and Staff Duties

A.C.N.S.

Tactical Section

Air Section

Gunnery Division

Torpedo Division

Secretariat and Staff Registries.

The duties of the C.N.S. and principal officers are as follows:

C.N.S.—All large questions of naval policy and maritime warfare organizations, distribution, and fighting sea-going efficiency of the fleet. Advice as to general direction of operations of war. Inter-

promoting effective cooperation in the work of the Department. Under Secretary Daniels, who succeeded Secretary Meyer in 1913, the offices of aid for personnel and aid for inspections were discontinued, but there was created the office of aid for

Education, whose duties were concerned with the Secretary’s programme for furnishing free instruction to enlisted men.

The outbreak of the World War gave new force to the proposals for reorganizing the naval administration, and by the Act of March 3 1915 Congress created the office of chief of naval operations, the incumbent of which by the subsequent Act of Aug. 20 1916, was promoted to the rank of admiral and assigned 15 officers above the rank of lieutenant-commander of the navy or major of the marine corps as assistants. The chief of naval operations was charged with the operations of the fleet and with preparation and readiness of plans for its use in war. By regulation his duties were defined as including the direction of all strategic and tactical matters, organization, manoeuvres, target practice, drills and exercises and the training of the fleet for war. Under his direction were also placed the Naval War College at Newport, the office of naval intelligence, the office of gunnery exercises and engineering performances, the operation of the radio service and other systems of communication, the aeronautics service, the division of mines and mining, the naval defence districts and the coastguard when operating with the navy. The duties of the previously existing bureaus were limited to activities subordinate to the fleet operations. By the Act of June 30 1914, these bureaus had been reduced to seven, the bureau of equipment having been abolished and its duties distributed among the other bureaus. The value of the new method of organization became almost immediately apparent; within 10 months after the passage of the first Act of 1915 plans for the mobilization of the U.S. naval force were approved and ready to put into effect. Thus, when the United States entered the World War the Navy Department was, from the administrative standpoint, well prepared to undertake its new duties and responsibilities. In his report for 1918 Secretary Daniels stated that the war had necessitated no change in the organization of the Department, which had easily expanded to meet the emergency. During the war the Navy Department had the assistance of the War Industries Board, the Council of National Defense, the National Research Council, the Aircraft Production Board and the Naval Consulting Board.

The Naval Consulting Board, composed of civilian inventors and engineers, was first established in 1915 with Thomas A. Edison as chairman. It was a voluntary body whose function was to give expert advice when called upon. Secretary Daniels also established an advisory council composed of Assistant Secretary of the Navy, the chief of naval operations, the chiefs of bureaus, the major-general commandant of the marine corps and the judge-advocate general of the Navy Department.

Secretary Daniels’ interest in education for enlisted men has already been noted. An order issued by the Navy Department in Dec. 1913 provided for instruction of enlisted men, petty officers and warrant officers serving on board ship, the purpose being partly to supply deficiencies in school training and partly to fit them for promotion. Training was also instituted at the various naval stations, and schools for assistant paymasters, yeomen, cooks, bakers, commissary stewards, hospital apprentices, machinists’ mates, musicians, mess attendants, painters, plumbers, electricians, blackssmiths, and carpenters were maintained. Thus enlisted men could prepare themselves to engage in civil trades at the end of their period of naval service. With the outbreak of the war much of this educational work was temporarily suspended. By the Act of Dec. 20 1917 the number of midshipmen at the U.S. Naval Academy was fixed as follows—five in each class for each year for four years and two in each class for every other year for four to three years; in 1919, however, the full four-year course was resumed. During the participation of the United States in the World War three training camps for officers of the marine corps were held in accordance with the Naval Militia Act of 1916, which granted the United States organized divisions of the U.S. Naval Volunteers, to which were assigned naval officers as instructor-inspectors of the militia. A later Act (Aug. 20 1916) created the U.S. Naval Reserve, the forerunner of which, in 1918, the naval militia was amalgamated. The Act of 1916 also provided for a Naval Flying Corps, for special engineering officers, for Naval Dental and Dental Reserve Corps, and for taking over the lighthouse service in time of war.

The Naval Appropriations Act of 1915 repealed section 9 of the Personnel Act of March 3 1899, which authorized the retiring of
officers in certain circumstances for the purpose of accelerating pro-
motion. War loans were new in that they were not made to the ordi-
missioned personnel of the navy except through vacancies created
by death or statutory age-limit retirements. In 1917, however, a new
law changed promotion by seniority, so that line officers above the
rank of commander could be promoted by selection. Sponsored by selection,
the question of proved ability being the controlling consideration. Much
comment was aroused in 1919 when a new fleet organization was put
into effect, by which a division of practically equal strength, the
Atlantic and the Pacific fleets, each having a commander-in-chief of the rank of admiral, were created. Some critics regarded this
as a violation of the principle enunciated by Admiral Mahan that
the fleet should never be divided. Secretary Daniels stated that
with the Panama Canal open the two fleets could effect a junction in
either ocean and “carry out the plans already formulated for opera-
ting as one fleet before any enemy could try conclusions with us.”

ADOR, GUSTAVE (1845–), Swiss statesman, a member of
a family of Vaud, which in 1814 obtained the burghership of
Geneva, and grandson of Jean Pierre Ador, who first obtained
the title, was born at Geneva Dec. 23, 1845. He studied
law at the academy (now the university) of Geneva and in
1868 became an advocate. In 1871, he started his political care-
er as member of the communal council of Cologny, and was
twice mayor, in 1878–9 and 1883–5. He was a member of the
cantonal Parliament 1874–6, and continuously from 1878
to 1915 save for a short break in 1902. In 1878–9 he represented
Geneva in the Swiss Conseil des États. Then he became a
member of the executive of the canton of Geneva, being put in
charge of the Department of Justice and Police. He resigned
after an unfavourable election in 1888, but once more became
member of the cantonal executive in 1885, and for 12 years had
charge of the cantonal finances. In 1889 he became a member of
the Swiss Conseil National, and remained so till 1917, being
elected its president in 1901. He was president of the cantonal
executive in 1890, 1892, and 1896. In 1894 he became lieutenant-
colonel in the Swiss army. In 1914 he founded in Geneva the
association for facilitating communications between prisoners-of-
war and the central Geneva agency, and succeeded in giving this
enterprise great importance and a wide-spread extension. After
the enforced resignation of Arthur Hofmann, Ador, in order to
aid the Swiss army, became a federal councillor or member of the
Federal Executive in June 1917 and was entrusted with the
Department of Foreign Affairs. Towards the end of 1918 he was
elected by Parliament to be the Swiss President for 1919, but
retired from the Federal Executive at the end of his year of office.

ADVERTISEMENT (see 1.235)—The great public service
rendered by advertising during the World War was one of the
most striking features of the progress made in this form of
business during the decade 1910–20.

Before 1915 to Government in modern times had attempted
to rely upon its own ability to float a loan through the persuasion
of commercial advertising on a large scale. The custom was
merely to publish the prospectus, and leave it to the investor to
form his judgment of its merits. It was not till the floating of the
4½% War Loan in 1915 that the British Government took any
definite steps to depart from precedent. At an early stage in its
subscription, when it was feared that the result would not be as
good as had been hoped for, a Treasury official asked the advice of
a well-known London journalist, and at his suggestion it was
decided to spend £100,000 in advertising under his direction.
A little more than £60,000 was actually spent in advertising, and
the subscriptions to the loan eventually realized nearly
£600,000,000. Later, this new departure was followed, but only
after stereotyped official methods had again proved inadequate,
in the campaigns for National War Bonds after Dec. 1916,
by a considerable extension of advertising, while in the United
States it was freely employed in the raising of the Liberty Loans
(see War Loans Publicity Campaigns).

Before this, advertising by poster had been employed ef-
effectively in England to gain enlistments for the army. In this
connexion, and in the loan advertising of 1915 and following years, both in Great Britain and America, advertising reached an
effectiveness that has not been approached before. It is true that the subject dealt with was in everyone’s mind; the
appeal was to patriotism, to emotion as well as to cold reason
and self-interest. The interests of the writer and of the reader of
the advertisements were identical. Even so, the results were
amazing. In 1917 a leading American banker said it was im-
possible to float a loan of $5,000,000,000 because there were
only 275,000 investors in the country.” But after widespread
advertising there were more than 6,000,000 individual sub-
scribers to this loan, and the amount was greatly over-subscribed.
For the last of the American war loans, the “Victory Loan”
flown after the Armistice, nearly 21,000,000 subscribers were
obtained—one for every five of the country’s population, in-
cluding women and children.

War advertising enlisted much new talent in writing and
illustrating. The foremost artists and writers on both sides of the
Atlantic volunteered their services and competed for the
honour of having their productions used. With professional
advertising men, printers, engravers and designers all, the
best, the result was an excellence in form and character that
had never been achieved before. While the tide of patriotic
emotion raised by the war brought new resources to advertising,
their proper application would not have been possible without
the knowledge gained in advertising for ordinary business
purposes during previous years (see Propaganda).

In the years before 1915 remarkable advances had been made.
The number of articles of trade-marked, advertised merchandise
had increased rapidly. Stimulated by advertising revenue, scores of
weekly and monthly publications had obtained circulation
running into hundreds of thousands, and some had passed
the million mark. Great daily newspapers had a similar growth
and could afford to sell their copies at a price which did not pay for
the paper on which they were printed. Posters and advertising
signs had passed from their former rude state to a high degree of
attractiveness.

At the same time came a remarkable improvement in the
character of advertising. Misleading advertisements and
advertising of questionable merchandise or of uncertain financial
offers were gradually weeded out. Publications found it
impossible to accept advertisements which were offensive or
untruthful. The Association of Advertising Clubs of the
World adopted “Truth in Advertising” as their slogan, and
vigilance committees were appointed to eradicate misleading or
untruthful advertising of whatever products. Advertising had
become a business of high principles and well-defined ethics.
One of the most powerful influences in the development of
advertising along sound business and ethical lines was the
advertising agency. Beginning more than half a century before as an
agency for the selling of space in publications, the modern
advertising agency grew into a service institution, acting on
behalf of its clients in planning advertising campaigns, selecting
the mediums to be used, preparing advertisements, attending
to all the details of engraving, type-setting and plate-making
and performing many other incidental services. The advertising
agency attracted well-educated young men in increasing
numbers and represented a recognized field for the employment of
talent.

All advertising is more or less a competition for public attention.
As the volume of advertising increased the competition
became more keen, and resulted in improvement of both the
writing and artistic treatment of advertisements. One of the
most notable features in recent years has been the use of illustra-
tions in colour, made possible by improved processes of colour-
engraving and by the perfection of high-speed colour printing
processes. One popular magazine in America, with a circulation
approaching two million; has contained more than 50 full-page
advertisements in colour in a single issue. Every one of these
pages was printed by four-colour process, and gave a faithful
reproduction of the subject. This has made it possible to display
different sorts of merchandise, including foods, in their natural tempting
colours, and textiles with all their shades and patterns, as well as
to reproduce beautiful paintings for their attractive value.
Perhaps the most remarkable result of this achievement is the
improvement in the artistic worth of advertising illustrations. Celebrated painters and illustrators no
AEHRENTHAL, ALOYS LEXA VON

longer find it beneath their dignity to make pictures for advertising purposes, especially as the bids for their services run to large figures. Similar improvement has been achieved in typography, engraving and lithography, and in all the mechanical processes of reproduction.

As the volume of advertising expenditure has grown, so has the number of publications which derive their chief support from advertising. These publications have been divided more and more in recent years into groups or classes, each with an appeal to a certain class of the population. The number of general publications reaching all classes has been correspondingly reduced. The most prominent class publications are the women's magazines, chiefly of monthly issue, of which in 1921 there were four or five in America with more than a million circulation. These magazines deal with home problems, dressmaking, cooking, care of children and kindred subjects, and are the most valuable mediums for the advertising of foods, textiles and household commodities. There are similar class publications devoted to business interests, the world of books, motion pictures, the theatre, fashionable society, sports of one kind and another and all classes of commercial and industrial enterprises. The significance of this tendency is that advertising of each kind may be placed before the readers it especially interests, with a selected audience and less waste of circulation.

Each succeeding year has seen some enlargement of the possibilities of advertising. Paid space has been used in increasingly large amounts in political campaigns, local and national, presenting the records of candidates and showing photographs of themselves and their families. It is used more and more to influence public opinion on behalf of one cause or another. Industrial disputes, involving strikes or lock-outs, have led employers and employees alike to appeal through advertisements to the public for sympathy and moral support. Public service institutions have used advertising to put themselves in a better light before the public or to explain the necessity for increased revenue. In one notable case, advertising was used to turn business away. The American Telephone & Telegraph Co. was seriously affected by the entry of the United States into the World War. It could not obtain the supplies it needed; the Government took thousands of its highly trained workers, and at the same time demands on its service increased enormously. The Company was wise enough to advertise, explaining why its service was deficient, why applicants were kept waiting for installations, and also implored the public neither to conduct unnecessary conversations over the wires nor to prolong use beyond the time required. Similar advertising was employed by the American railways in the period immediately following their return from Government control to private management, but in this case the explanation of inadequate service was followed by an appeal for higher passenger and freight rates to provide revenue for rehabilitation. During the same period, the Chicago meat-packer, facing threatened Federal action for the further regulation of their activities, entered upon an elaborate advertising campaign to convince the public of their blamelessness. All these varied developments of advertising have been of the utmost interest to students of economic trends. It is certain that advertising has been largely instrumental in changing buying habits and in introducing many things which have quickly become a part of everyday life. The chief function of advertising is the saving of time. Information, whether as to merchandise or as to services or public issues, can be placed before great numbers of the population almost over night. Public education on any subject can be effected in days or weeks, where years were required by old-fashioned methods of canvassing. For this reason it has been possible to build up entire new industries on advertised products within a short period. In political life, and in financial operations, advertising has served to eliminate the secrecy and ignorance which invite deceit and fraud. The whole tendency is to take the public into confidence and play the game in the full light of fair and frank publicity. Advertising is no weapon for dark causes and no advocate for rates. To be effective it must be a sincere expression of the character of the advertiser. Unless it bears the stamp of truth and sincerity it is ineffective and defeats its own purpose.

This individuality of a business house as well as the conditions under which it operates and the field from which it may seek custom must all be considered carefully before embarking on an advertising campaign. It is well to seek the expert assistance of an advertising agency of established reputation. The implements of advertising are many, including newspapers, weeklies, magazines, trade publications, outdoor displays, cards in railway cars and the sending of circulars and booklets to persons whose names have been selected on some sound principle. Each is more efficient for one purpose than another, and knowledge and judgment are needed to plan a campaign that will achieve results at economical cost. The advertising policy of a business house and the selection of an advertising agency and advertising manager should be a concern for the executive heads who direct the permanent interests of the business. For advertising, once entered upon, is a continuing influence. The advertising for any one week or any one month, unlike that week's or month's buying or selling, cannot be regarded as a completed transaction. Advertising, it already has been said, is an expression of character. It reveals the character of the advertiser, and immediately begins to form a consciousness of the particular house or merchandise advertised in the mind of the public. It has an influence also on the advertiser's own organization. The workman in the factory and the salesman in the shop judge from the advertising their employer's sincerity and desire to serve. If the advertising is such that they can take pride in it; if it is attractive in appearance; if it is placed in the right environment; if it is a worthy representation of the purposes and ideals that animate the business—then the advertising will stimulate every employee to greater efforts and enhance the moral of the organization. Every advertisement tends to create or destroy the one great business asset, reputation.

The steady growth of advertising is assured. While there are no authentic data on the amount spent for advertising, it has been estimated that the expenditure for all forms of advertising in America in 1920 was upwards of $4,200,000,000, an increase of approximately 100% in five years. Individual industrial firms in Great Britain spend as much as £2,000,000 a year on advertising, and the total expenditure there on all forms of publicity is estimated at over a hundred million sterling annually. With the growth in public intelligence and the realization of the power of advertising, it is likely to be still more widely employed in the future. The modern business concern is adopting advertising as a part of its fixed business policy; not as an expedient for occasional use but as an element of business to be constantly employed.

Aehrenthal, Aloys Lexa von, Count (1854-1922). Austrian-Hungarian statesman (see 3,257,095), was born at Gross-Skal, Bohemia, the son of Baron (Freiherr) Johann Lexa von Aehrenthal and his wife Marie, née Countess Thun-Hohenstein, and began his diplomatic career in 1877 as attaché to the Paris embassy under Count Beust. He went in 1878 in the same capacity to St. Petersburg, and from 1883 to 1888 he worked at the Foreign Office in Vienna under Kalnoky, with whom he formed close relations. In 1888 he was sent as councillor of embassy to St. Petersburg, where he exercised considerable influence with the ambassador, Count Wolkenstein. Recalled in 1894 to serve in the Foreign Office he undertook important duties, and in the following year went to Bucharest as ambassador. Here he succeeded in strengthening the relations between the courts of Vienna and Bucharest, the secret alliance which King Charles had concluded in 1883 with the Central European Powers being renewed on Sept. 30. In 1899 he became ambassador in St. Petersburg, where he remained until his appointment as Foreign Minister in Oct. 1906. Aehrenthal at this time thought that Austria-Hungary must, even at the cost of some sacrifice, come to an agreement with Russia. In this sense he endeavored to continue the negotiations successfully begun by his predecessor, Prince Franz Liechtenstein (b. 1853), for the bridging over of the differences on Balkan questions.
between Vienna and St. Petersburg, in order to create a basis for a permanent friendly relation between Austria-Hungary and Russia. He played a principal part in concluding the Mürzsteg Agreement of 1903. During the Russo-Japanese War he took a strong line in favour of a benevolent attitude on the part of the Vienna Cabinet towards Russia. When, in Oct. 1906, he succeeded Count Goluchowski as Foreign Minister he at first maintained the views which he had professed as ambassador. He was determined to preserve the interests of Austria-Hungary in the Balkans, but also showed himself prepared to meet the Russian wishes in the Dardanelles question. Accordingly he entered into negotiation, after the outbreak of the Young Turk revolution in the summer of 1908, with Isvolski, arranging with him Sept. 15 at the château of Buchau, in Moravia, an agreement which aimed at securing for Austria-Hungary the annexation of Bosnia and Herzegovina and for Russia the opening of the Dardanelles to Russian warships.

It was only when Isvolski's proposals were wrecked on the opposition of England, and the Russian minister protested against the annexation of Bosnia and Herzegovina, which had meanwhile been accomplished, and supported the Serbs in their opposition to Austria-Hungary, that Aehrenthal abandoned the idea of a friendly accommodation with the Russian Government. In the sharp struggle during the annexation crisis, not only with Russia and Serbia, but with the Western Powers, he held with tenacious energy to his purpose, and, powerfully supported by Germany, succeeded in carrying out his intentions after excited negotiations which threatened to lead to war. The annexation of Bosnia and Herzegovina was acknowledged by the Powers; an agreement was reached with Turkey; Serbia, after long hesitation, was obliged to submit. For this achievement Aehrenthal was rewarded by his master by elevation to the rank of Count (Aug. 18 1909), while at the courts of his opponents he was hated but respected.

This was the zenith of his political career. Few at this time realised the danger which arose later from the closer adhesion of Russia to the Western Powers, especially as Aehrenthal took the greatest pains to prevent all quarrels. After the conclusion of the annexation crisis, that Austria-Hungary cherished no far-reaching plans of conquest. In this spirit he offered the most decided opposition to those circles at the court of Vienna which advocated a bloody reckoning with Serbia. He held fast by the Triple Alliance, for he saw in this the surest bulwark of peace. He sought to form the most intimate relations with the German Empire, but insisted on the independence of the Habsburg Monarchy, and energetically repulsed all efforts on the part of the German chancellerie to set limits to that independence. One of his most difficult tasks was to adjust the ever-recurring conflicts with Italy, who, while officially supporting the political action of the Triple Alliance, often embarked in enterprises directly opposed to the interests of Austria-Hungary. A succession of agreements which he concluded with the Italian Foreign Minister, Tittoni, justified his efforts, and enabled him to maintain correct relations with the Italian Government. Yet, by the maintenance of his peace policy, which had the full approval of the Emperor Francis Joseph, he came into serious conflict with the party led by the chief of the general staff, Conrad von Hötzendorf, which championed a policy not afraid of energetic, warlike methods. The battle, carried on on both sides with tenacious endurance, ended in 1911 with the victory of Aehrenthal and the resignation of Hötzendorf.

In the solution of questions of internal policy Aehrenthal, as Foreign Minister, only took part in so far as they seemed to him to affect the interests of the monarchy as a whole. With the Czechs, who on his accession to office had shown some suspicion on account of his intimate connexion with the leading members of the loyal Bohemian landed aristocracy, he succeeded in maintaining reasonably good relations. As against the Magyars, he upheld the view that the unity of the monarchy must not be shaken, and he therefore offered a determined resistance to the annual budget proposals of the independent seapower party, which in the end defeated the undertaking. He saw that the interests of the Crown in military matters. He realized the need for an increase of the army and the reorganisation of the army and navy, but he opposed the far-reaching demands of the War Minister and the chief of the general staff.

Even during his lifetime the estimate of his political policy fluctuated violently. On the one hand it was blamed as provocative, on the other as weak. After the disastrous result of the World War, bringing with it the downfall of the Habsburg Monarchy, it is still more difficult to answer the question whether the path pursued by Aehrenthal in foreign affairs was the right one. It is certain that the Entente Powers were drawn more closely together by the active part played, during his period of office, by Austria-Hungary in Balkan affairs. It is true that the chances of success for the Central Powers in an international struggle were better in the years 1900 and 1911 than in 1914. But the question remains undecided whether, if his activity had been longer continued, Aehrenthal would have been able to maintain the position of Austria-Hungary as a great power without an appeal to the decision of arms. There is no doubt that Aehrenthal was a statesman of considerable mark, a man of wide knowledge and well-ordered intelligence; he was ambitious, but not vain, and an untiring worker. Moreover, in moments of great excitement he was able to maintain outward calmness. He was convinced of the own value, but had no desire to parade it. The Emperor Francis Joseph esteemed him, stood by him in the good and evil hours of his administration of foreign affairs, and repeatedly refused to accept his tendered resignation.

See B. Mollen, Alois, Graf Aehrenthal: Sechst Jahre auswärtiger Politik Oesterreich-Ungarns (1917); and the article "Aehrenthal" in the Deutsche Nekrologien (vol. xviii., 1917, pp. 230 seq.).

(A. F. P.)

AERONAUTICS (see 1.250).—Between 1905 and 1921, Aeronautics, an infant to start with, had not grown as a child grows, but irregularly. One member had prospered at the expense of another. Thus we find that enterprise in flight was early in advance of all appliances; then engines developed for a period; later, structural design. Though aerodynamic theory had been far ahead it was badly neglected for a spell and was once again fostered, with this study secret and semi-magical wing shapes disappeared; after that came methodical production, first in units and subsequently in bulk; then came piloting and the elements of commercial flying. The seaplane, though less risky than the aeroplane, advanced even more fitfully and never caught it up; the airship, which seemed simple and safe, was still lagged behind because it made less appeal to sensation and cost much more. The engine, though once in advance, fell behind, and only now (1921) is again full of promise. Landing-gounds and night alighting facilities have advanced but little. Meteorology progresses slowly against fog, the enemy, but aerial navigation is at last appearing as a science.

By taking such of these elements as have separate stories and keeping them distinct in the several sections which follow, it is hoped to present more clearly the progress and prospects of aerial science than by showing a series of moving pictures of the infant prodigy in motion as a whole.

Achievements and Performance (see Section L).—The twelve years of labour of the American Wrights culminated just before 1909 in the birth of the art as we now know it. Hazardous flights on the straight or in figures of eight; a circle over Paris; the crossing of 24 miles of sea; the exceeding of the speed of an express train; a velocity once deemed monstrous and now insignificant; the scaling of the Alps; looping and inverted flying; leaving the craft by parachute; released first 1,000-lb. weight; firing the first gun; discovering how to get out of a spin; alighting by night, etc.—each of these was an experience and a token of growth. Each seemed perilous and astonishing, yet they had become so common by 1921 that we no longer remember the sense of wonder they caused.

Design (see Section L).—The advance of design occurred away from the public view, nor were its milestones of progress coincident with any of the remarks made by the great performers who relied more than ever on their own tact in skilful flying, and thence to consider the capacities of their craft. They shied under the cautions of those who made stress calculations. Each "stunt" was performed before any human being knew if it was safe. How and why was design altered
AERONAUTICS

and battled under the circumstances? Yet strength factors were introduced, and the aeroplane, its frame, its‘other fine lines provided, wing shapes and controls improved, alighting gear developed and instability cured. This is the subject matter of Section II, which is closely allied to Section I. **Aeronautics (see Section III).**—Aerodynamic theory had risen out of the void at the bidding of the applied mathematician before 1909, but it developed at the call of designers who would have been tied to the foreseen or found methods of construction. Once aerodynamic theory was established their inspiration could take wing.

The deductions from wind tunnel experiments on models of long span, before the war were no output of aircraft in Britain other than by units; in France there was some manufacturing, in America a little, and in Germany rather more. These countries had factories producing aircraft on a process; but the production, even in numbers, was deemed in Britain to need correspondingly few aircraft. A large navy neglected them. When bulk production came it came with a will, but designs that were admirable for unitary construction could not be adapted to bulk manufacture, and the British story of changes in material and methods which is outlined in Section IV, is typical of the war period everywhere.

The tunnelling of fabrics with cellulose acetate, the evolution of the faired strut and wire, the stearable tail skid, the wing in which he has indicated the arrangement in Section VI, and greatly advanced the problems. It was E. T. Bisk in 1915 in his own person as flyer verified the theories he had formed and achieved stable flight with an American balloon. Lighter-than-air craft came practical flight; France in model experiments, rotary engines and speed records; Germany in length of aeroplane flight and in rigid and semi-rigid aeroplanes. At the end of the war the growth of both model and full scale, Britain took the lead before the war and still kept it in 1921. Something of each national temperament is disclosed by these specializations.

**Aircraft (see Section IV.).**—Aircraft constructional methods are to be regarded from two points of view: the one where a few craft are to be made as perfect as possible, and the other where bulk production is demanded.

The faired strut and wire, the stearable tail skid, the wing in which he has indicated the arrangement in Section VI, and greatly advanced the problems. It was E. T. Bisk in 1915 in his own person as flyer verified the theories he had formed and achieved stable flight with an American balloon. Something of each national temperament is disclosed by these specializations.

**Aircraft (see Section IV.).**—Aircraft, constructional methods are to be regarded from two points of view: the one where a few craft are to be made as perfect as possible, and the other where bulk production is demanded.

Bodies like the Royal Aero Club in Britain exist in each country and meet annually for these purposes.

**Seaplane (see Section VII).**—The seaplane is relatively backward. To make a craft light enough to fly and heavy enough to stand the buffets of the open sea up to the speed needed to quit the waves in flight is a problem which was not fully solved even under the most favorable conditions. As when, for example, an aeroplane and to those approaching them when they are immersed in fog and will afford facilities for night alighting. The movement is in this direction. The mobility of aircraft makes international agreement on all rules for alighting, ranking, and signalling warnings very important.

**Airship (see Section VII).**—Airship knowledge gave to Germany technical advantages which would have been even more valuable to Britain. They did not use on aeroplanes the identical engines of their airships; but the life of large aeroplanes of the utmost reliability and economy was there. The dominant advantages of airships are that they fly for long hours, carry large loads, do not descend for an engine failure and can safely fly by night. In connection with this and the Berlin Convention, they are able to fly, for the aeroplane in speed from point to point. High cost of housing and the numbers required to handle them on the ground were their chief hampering factors, but the wonderful development of the materials and devices has improved the position. The towing of airship by airship and by submarine, the protection of fabric from deterioration, the use of non-inflammable gas are all factors which have contributed to large further advantages. They are also incidentally much speeding-up of processes and methods, the evolving of glives and cements, fine castings, new alloys and the widespread use of plastic. There is no mention of the World War demonstrating the science of aeronautics rather than that it fostered it. The war did foster the tactics of quantity production.

**Aeroplane Engines (see Section V).—Man would have flown long before he did but for the lack of a light engine. One cwt. per horse-power was about the weight of the commercial gas engine, and to fly he wanted one twenty times lighter. The French rotary engine of 1904 was the first real triumph of the internal combustion engine, for at 5 ft. 4 lb. a motor-car engine weighed ten. How and by what grouping of parts, increases of compression and refinements of design this weight has been cut down to 2 lb. with Fuji was the subject of the Section V. From this its sub-cells of the Germans on the basis of airship experience had inclined rather earlier than others to big powers on aeroplanes, and their aeroplane successes on aerodynamically inferior craft were due to big engines. Their engines were water-cooled, rather heavy but reliable. The radial air-cooled engine of the French has been mentioned above. The British service was late to realize how vital their engines must be, and developed aero engines non-rotary, and some good water-cooled motors eventually of adequate sizes. The Americans made good use of the experience poured in upon them from Europe when they began in 1917 to try to build an American four-cylinder, 350 h.p. engine. The advances in view to-day are considerable. The means for protecting ourselves from the fire risks on crash due to petrol are also being evolved, and the end is the flying automobile, a subject from the ground in view, developed tardily everywhere, though first in Britain. It was a surprise to find that raiding airships from Germany disclosed no up-to-date navigational apparatus when they were brought down. They had these emergency signals to guide them when immersed in cloud or fog. Even after seeing the Lucas compass (see Plate I, fig. 2) on captured aeroplanes they did not know what the principle of the the space-damped vertical card, spherical bowl and lead core, nor that anywhere an instrument to compare with the British apparatus figured in Section VI. The air speed indicator that uses the principle of the anemometer was the only instrument of the kind in use. The early war was fields and each flier a law to himself. When the Air Convention of Oct. 1919 is ratified all aircraft will be taboo that have not a specific factor of strength and an adequate field of view (section VIII.1). As with anything, there is a limit to the speed to which is increased the comfort, and they are approaching the time when they are immersed in fog and will afford facilities for night alighting. The movement is in this direction. The mobility of aircraft makes international agreement on all rules for alighting, ranking, and signalling warnings very important.
mized in aircraft research. Only individuals in any army, navy or populace appreciated it. Its exponents were a butt for attack.

Still it was war or the fear of war that was responsible for what there was. War has often been the great inciter of technical advances—it accounted for the Roman roads and for the modern steel industry when battleship plates were founded and forged. Such industries have in the past made some compensation to the world for their malignant first inspiration. So, too, will aircraft in its civilian uses as a means of many indirect advantages.

The exact calculation of stresses, the exact adaptation of material to meet them, the most radical economy of avoidable weight, all of which are in the essence of engineering progress, have been enforced upon the new engineer physicist of aerial science, and young and brilliant aircraft engineers have, since the Armistice, been thrown into industry generally, imbued with the exactitude and thrift of mechanical material learnt under the grave penalty attaching to small errors in strength, weight or quality or design for aircraft construction.

The introduction of the scientific idea was an intense uphill struggle. Flying was first in the hands of men of enthusiasm rather than of precision; the pioneers were more courageous than scientific or critical. Dynamic similarity, the theorem of three moments and the like were uninteresting to the small makers, and all makers were in a small way. The data for the calculation of aeroplane stresses were insufficient to move the larger firms to quit the imitative methods of design which were the beginnings of the industry. The risks from obvious misadventures, from fliers' errors, from bad landing-grounds, etc., were so great that the hazards to be guarded against by calculations and wind-tunnel experiments appeared few and manageable by comparison.

Before the year 1912 pressure had a rather doubtful directing influence. If it was not explicitly said that such appliances must be frail and dangerous, it was assumed. In one country after another the ministers were rather upbraid by the air industry and dismissed eventually for failing to spread themselves on large orders that urged to develop the basis for strength and balance, by expenditure now proved justifiable on precise calculations, laboratory work and mathematics, finer metallurgy, woodcraft and chemistry, instruments and navigation such as are recorded in the succeeding sections.

The main efforts made on the scientific side have been individual, and for those individuals are mainly unrewarded. Many are dead—scarce heard of—E. T. Busk; K. Lucas; R. M. Groves; B. Hopkinson; Pilgrim; Pinsent; Usborne; many others lived on in 1921 to see the result of their work, which was unparalleled in brilliance of achievement. Fortunately the names of the performers of heroic flights live on, and many—unavoidably there are omissions from so great a list—appear in Section I.

In 1911-12 the compelling necessity for providing in the interests of fliers a margin of strength for aircraft, calculated upon the stresses induced by its speed and by its manoeuvres, was first accepted. So far as we know, this importation of an engineering standard was British, and was imposed upon foreign suppliers for the first time.

The various nations, each wanting to know how the other was getting on, would purchase a few examples abroad; a proceeding naturally coupled with any known precautions for the home flier whose person would be risked in testing them. In any country the industrials regarded foreign purchases with some jealousy, since a tenous air vote was seen to be expanded elsewhere than with the home constructor; still an informative exchange of technical knowledge was available in many indirect ways.

The 20 H.P. engine of Wright and the 35 H.P. engine of Green seen to be too small by any who knew the 50 H.P. Gnome in flight. The speedy monoplane of Nieuport (French 1910) showed Britain the value of smooth external lines for the craft. The Wright biplane (U.S.A.) bore only 2 lb. per sq. ft. of wing area, and Farman followed its lead in France. The uses of heavy loading, as in the De Haviland craft, appeared later, when its demerits were envisaged and difficulties, such as the high speed of sligtness, overcome simply by the great skill and courage of fliers. The German Zeppelin taught much to Britain.

The British Avro and BE2 taught the possibility of a wide speed range to the French and others, and generally aircraft lore became international.

(M. O'G.)

I. PERFORMANCE OF AEROPLANES, 1909-1920

The Arena of Aeronautics in 1909.—The achievements in 1909 had been latent in the effort of the previous 40 years; that which appeared sudden was the outcome of protracted experimentation and the driving force of great personalities. The chapbook in the guise of a novel then recalls the names of Wright, Voisin and Farman. The year 1908 had made power-driven flight a reality. Farman had flown from Châlons to Reims; Orville Wright had flown for an hour in America; Wilbur Wright held the Michelin Cup with a flight of 124 km. in France.

In 1909 man little knew at what bitter cost he would maintain the conquest of the air; yet the thrill of life served but as a stimulus. The International Conference that was held in London consolidated the position of the Aero Clubs of the various countries with a view to the advancement of aeronautics as an organized movement. The great natural flying-ground at Pau soon made itself the Mecca of aeronautics. There Wilbur Wright created the first flying-school, and among his pupils were names now famous. At the Aero show in London the public inspected and handled machines that really flew. At Farnborough, Cody was experimenting with a machine that was to glide down a wire. Blériot, who had emerged from crash after crash unscathed, flew from Étampes to Orleans, 25 miles. His little machine hopped over hedges and trees, its diminutive engine humming above the roof of the Paris-Orleans express, the windows of which were white with faces upturned to see the flying wonder. On a memorable Sunday morning (July 25 1909), Blériot set out from France without a watch or compass to fly the Channel; his monoplane was lost in the haze; but he emerged triumphant towards the cliffs of Dover, where he landed on a slope and crashed. His feat eclipses all others of the year, and is the forerunner of the crossing of the Atlantic 10 years later. The analogy goes further, for Hawker's failure to cross the Atlantic is reminiscent of that other failure of Latham's to wrest the prize from Blériot.

The year is memorable for flying meetings which roused public enthusiasm in many countries: at Reims, Brescia, Berlin, Cologne, Blackpool and Doncaster. At Blackpool on 26th May, 1909, the F. and B. E. Club, led by Cody and Lock, inaugurated "Aeronautics Week", with a fly past and gliding displays. The first flight was on 7th May, 1909, by the Wright Brothers. The flight over 5 miles lasted 3 minutes. The Wrights were awarded the Kite Prize of £1,000

The Flying Qualities of the Early Aeroplanes.—So rapid has been their development that it is worth recalling what these early aeroplanes were like. The factors which govern the balance of an aeroplane and the respective functions of the movable and fixed surfaces used for its control during flight were, in 1909, ill understood. The probable, possible and impossible were all one.

The peculiar features of an aeroplane may be grouped under four headings:

1. The engine, and the way in which its power is transmitted to the propeller
2. The frame, and the way in which it is supported
3. The air-screw, and the way in which it is driven
4. The control, and the way in which it is used

The engine is the heart of the aircraft, and is the source of its power. It is also the source of its noise, and is therefore very important in the design of the aircraft. The frame is the skeleton of the aircraft, and is the support for the engine, the air-screw, and the control. It is also the source of the aircraft's strength, and is therefore very important in the design of the aircraft. The air-screw is the source of the aircraft's thrust, and is therefore very important in the design of the aircraft. The control is the source of the aircraft's stability, and is therefore very important in the design of the aircraft.
The Pre-War Years.—The chief flight of the year 1910 was Paulhan's from London to Manchester, by which he won the Daily Mail £10,000 prize (April 27 and 28 1910). The race was gallantly contested by Grahame-White. His skill and tenacity had been the determining factor; the prize would have been hard to award. The chances of the race aroused the greatest enthusiasm and to the many incredulous one more demonstration was thus given of the possibilities of the aeroplane.

During the year flying meetings were held at Helipolis, Wolverhampton, Bournemouth, Blackpool and Lanark, the flying performances at which demonstrated the advance that had been made on those of the previous year. At Bournemouth England lost one of her best fliers, the Hon. C. S. Rolls, who had previously made the double journey across the English Channel. His statue stands at Dover, gazing out over the waters that he crossed. Most British pilots were flying on aeroplanes that were wholly or partly French, but it is to be noted that Moore Brabazon won the British Michelin Cup with a flight of 19 m. on an all-British machine. At Lanark Chavez on a Blériot monoplane reached a height of 1,704 metres, a prelude to his magnificent flight over the Alps, the tragic sequel to which was his fatal accident on landing. Legagneux, however, created a record by reaching a height of 3,100 metres.

Moissant flew from Paris to London but, though he quickly reached English soil, various troubles delayed his arrival in London till three weeks later. On the continent, Leblanc won the £4,000 prize for the Circuit de l'Est. Grahame-White went to America and brought back the Gordon Bennett Cup, which Curtis had won the year before. The contests for the British Michelin Cup and the Baron de Forest prize brought forward new fliers. Sopwith, competing for the former, flew 100 m. at Brooklands, which had been opened as a flying-ground the year before, thus beating Cody's distance of 97 m. which had previously stood; competing for the latter he flew from Eastchurch west into Belgium.

At the close of the year Cody, after an exciting contest with Sopwith and Ogilvie, held the British Michelin Cup with a distance of 185 m. in 4 hours 47 minutes. In France Tabuteau held the International Michelin Cup with a distance of 582 km. in 7 hours 48 minutes.

It was in 1911 that the aeroplane was first tried in warfare. Hamilton, an American, carried out a flight over the town of Ciudad Juarez during a Mexican rebellion. In their campaign in Tripoli the Italians also realized the value of the aeroplane for reconnaissance. In England the idea of the time was that, for bombing, aircraft would be useless and contrary to international usage; on the other hand, the first British attempt was made to run an aerial post between Hendon and Windsor.

Capt. Bellenger, a Frenchman, flew from Paris to Bordeaux in 5 hours 10 minutes net time, a distance of 600 km., while later Fourny remained in the air for 11 consecutive hours, covering a distance of 720 kilometres. Garros made a height record of 3,010 metres. London was linked with Paris by a notable non-stop flight by Prier, which foreshadowed the aerial services of to-day.

The year 1911 saw many races: the Paris-Madrid race won by Védères at 50 m.p.h., in the course of which the French Minister of War met his death and the premier was seriously injured; the European Circuit, divided into nine stages, with the recently opened Hendon flying-ground at the end of the seventh, which was won by Lt. Conneau flying under the name of "Beaumont"; the Daily Mail race round Great Britain of 1,010 m., also won by "Beaumont" with Védères as a close second.

The Gordon Bennett Cup was won for America at Eastchurch by Weyman flying a Nieuport monoplane at 70 m.p.h., and the International Michelin Cup for France at Gidy-Lhunbery by Helen with a distance of 1,252 km. in 14 hours 7 minutes at 56 m. per hour. The increase in performance over the previous year may be referred chiefly to the development of the aero engine. It would be difficult to say that fliers were more skilful, but it is certain that they were able to substitute knowledge and experience for pure instinct, and thus set out on long and arduous flights with increased confidence in their own powers and in the reliability of the aircraft they flew.

One of the most prominent features of the year 1912 was the active part that the British and French Governments took in the development of aircraft for war. The French Minister of War held a great review of military fliers and aeroplanes, and British aircraft took a conspicuous part in naval and military manoeuvres. The Cody pusher biplane won the £4,000 prize in the War Office trials on Salisbury Plain in the summer, during which the tractor biplane BE2 reached a height of 9,500 feet. In Sept. four army fliers lost their lives in two accidents in monoplanes, which led to close restrictions being placed on their method of bracing in England. In March the French Government had imposed a ban on certain monoplanes until the defects were removed as the result of a report by Blériot on their structural weakness.

Garros won the Grand Prix of the Aero Club de France for the Anjou Circuit of 685 m. at 45 m.p.h.; Sopwith the first Aerial Derby at 50 m.p.h., a race round London of 81 m.; Védères the Gordon Bennett Cup in America in 105 m.p.h.; Audemars flew from Paris to Berlín; the two British Michelin Cups were won by Hawker and Cody, the first with a duration of 8 hours 23 minutes, and the second with a flight over a circuit of 186 m. in 3 hours 23 minutes; in France Daucourt for the Pommery Cup flew 350 m. in a single day at 63 m.p.h., while at the meeting at Leipzig Hirth reached a height of 4,100 metres. World's records were made high by Garros, who climbed to 6,160 metres in distance by Fourny with 1,070 km.; and in speed by Védères with 174 km. per hour, over 5 kilometres.

In the spring, flying had suffered an irreparable loss in the death of Wilbur Wright from typhoid fever.

Apart from the establishment of the fundamental merit of the tractor biplane the year was notable rather for a steady improvement in strength and detail than for any radical departure in type. From this time it becomes increasingly difficult to single out individual performances. Achievements deemed impossible three years before became commonplace over the next.

The year 1913 was one of great progress. Long-country flights were proving day by day the faith that fliers had in the aeroplane. Seguin in France covered 1,021 km., Legagneux reached a height of 6,120 metres, while Prévost attained the speed of 203 km. per hour, over 5 kilometres. It was a brilliant year for him; he won the Schneider Cup for seaplanes at Monaco, covering 750 nautical m. in 3 hours 48 minutes, and the Gordon Bennett Cup at Reims at 124 m.p.h. Helen won the International Michelin Cup with a distance of 16,000 km., Captain Longcroft won the Britannia Challenge Trophy by a record-breaking flight from London to Le Bourget via Bournemouth on a BE2 monoplane at 125 m.p.h. Garros won the Second Aerial Derby at 70 m.p.h., while Pécaut in France and England gave some of the most marvellous demonstrations in the new art of aerobatics that the world had ever seen, including looping, inverted flying and quitting his aeroplane in a parachute. In Dec. 1913 the RKI, the first aeroplane stable longitudinally and laterally, was flown for 35 minutes without hand or foot control; and this, which may be regarded as the greatest technical advance in aerodynamics, is to the credit of Busk, an Englishman, who both made the flight and applied the theory on which the aeroplane was designed. The last previous attempt of the kind was by Dunne, who a few months earlier had flown for one minute with "hands off."

The year 1914, just as it marked a turning point in the affairs of nations, altered the whole character of flying. For seven months the ideas of safe, stable flying and safe alighting were dominant; then the World War came down like a curtain and blotted them out in favour of widely different objects. During those months, Sykskia, in Russia, had been proving the weight-carrying possibilities of the aeroplane, and had risen to 300 metres, carrying 150 kilogrammes. At Farnborough, an SE.1 (see Plate I., fig. 4) flew at 130 m.p.h. and climbed 1,090 ft. in a minute. Linnekogel had reached a height of 6,350 metres in Germany, though just before the war Oelrich beat him by reaching 7,860 metres. Landmann
in Germany remained in the air for 21 hours 48 minutes, while Böhm further improved on this unofficially with a time of just over 24 hours. The Schneider Cup for seaplanes was won for England by Pixton, who covered 150 nautical m. in two hours at Monaco on a Sopwith biplane fitted with floats. The Aerical Derby, the London-Manchester-London and London-Paris-London races were all won by Brock. Notable events on the Continent were the Prince Henry Circuit of 1,125 m. in Germany, in which there were 40 competitors, and the Security competition in France; although most of the big international races had to be cancelled, the German races were held although afloat for speed at low heights suitable to the race-course or for the maximum climb was by no one appreciated as vital for war purposes, either in France or Germany, and least of all in Britain; aeroplanes were for reconnaissance—they should fly slowly—and the very inferior anti-aircraft guns would not impede their flying low; it was not till many months elapsed that the margin of speed and climb was found to be decisive as to who should be the victor in mortal combat held in the upper air. The diverse needs of war stimulated the development of specialized types, which were evolved as fast as production considerations would admit. The prime use remained, as foreseen, reconnaissance, but to maintain and support this other craft were called into being; the possibilities of the aeroplane as a bomb-dropper were as yet hardly called for. The early war pilot went into battle armed more as a sportsman than as a soldier. But he was attacked, and had either to be made self-defensive or to be escorted by fast, high-powered, swift-climbing fighters.

In 1915 the artillery on the ground came to rely almost entirely on aerial "spotting," and the small single-seater fighters had to sweep hostile aircraft from the skies to allow such machines fitted with wireless to pursue their work uninterrupted. Bombing was also rapidly developed. The first time a 1,000-lb. weight was released by Goodden from an aeroplane was an event calling for a special communication to the Secretary of State that by big bombs the nerves and arteries of the enemy might be continually harassed and disorganized. Owing to freedom of movement in three dimensions air supremacy was a far more difficult and comprehensive thing than naval supremacy. It was never achieved locally and for brief periods by any Power, and then only by concentrating organizations of the greatest mobility and flexibility in the same place and time.

The requirements of quantity, coupled with the demands for change, came so rapidly that the development and expansion of the aerial arms of the Great Powers are difficult to grasp. Of the innumerable acts of courage, the endurance and self-sacrifice, the skill of the pilot in war, it is impossible here to attempt a record. Here and there the names of great pilots stand out. But if one be mentioned, a hundred others would claim justice. Such were the changing fortunes of war, so many and so astounding were the feats of daring, that with deeds not unworthy of a Ball, a McCudden, a Bishop, a Nungesser, a Garros, a Guynemer, a Védères, an Innemann, a Richthofen, a Boedeker or a Voss, many a fighter passed through the war without fame or praise.

It was only during 1915 that the specialized type of aeroplane began to appear. The two-seater aeroplane with an engine of up to 150 H.P. was used promiscuously; for reconnaissance, artillery "spotting," any bombing there was, and fighting as well. Types in use by the British were B.E.2c's, Avros and Blériots, with small engines below 100 H.P.; by the French, Caudrons, Breguets, Farnoms, Voisins, Blériots and Moranes; by the Germans, LVG's and Rumplers, with engines over 120 H.P. and up to 160 H.P.; the maximum speeds seldom exceeded 80 m. per hour. Later in the year the single-seater, originally intended as a scout, was used for fighting. The 80 H.P. Bristol scout and other tractors used by the British were handicapped by their inability to fire forwards, the direction of best aim; the various models of Nieuport and Morane scouts used by the French were also adopted by the British, while the Albatross and Fokker scouts were used by the Germans. Engines up to 200 H.P. were coming in. The so-called "scout" became a real fighter; its speed and climb became truly effective when firing through the propeller was devised by a Frenchman, adopted by Germany, and then with feverish haste by the Allies. The French and Germans, more zealous about bombing, were for this purpose introducing large twin-engined aeroplanes and experimenting with armoured ones. Speeds rose to over 100 m.p.h., and aeroplanes flew and fought at heights of 15,000 ft., whether they were driven by the increasing intensity of the anti-aircraft fire and by the advantage to be derived from a swift descent to pounce or to retract. Night flying, which had been tentatively practised for exhibition before the war, was taken seriously as a potential weapon for bombing, for the depositing of spies and for other conveyance were realized. Stable aeroplanes with special alighting gear and a clear forward field of view were needed for the repelling of airships by night. The loading of war aeroplanes was increased and was only limited by the absolute necessity of reasonable landing speeds; even then fast scouts taxed the skill of most pilots. Seaplanes, whose aerial performance was always poor compared with that of aeroplanes, were of great use in conjunction with naval operations, and took part in the Gallipoli campaign.

In 1916 the air services came more and more into prominence. The German series of battleships and the British squadron were not so impressive an achievement as was insistent. The French Spad flew at 130 m.p.h. and reached over 20,000 feet. The German Albatross scouts manoeuvred magnificently at great heights, and high-flying reconnaissance Rumplers with cameras photographed back areas. Bombing flights up to 800 m. were carried out, notably by the French. Night bombing and even night reconnaissance became general, first on moonlight, and then, as the flyer's skill increased, on dark nights. Accessories for night flying, such as wing tip flares, were developed. Airships had already proved vulnerable to aeroplane attack, and a German airship was brought down in flames at Cuffley on Sept. 3, 1916 while engaged in raiding England by night. Kite balloons were attacked and brought down with incendiary rockets and bullets. Flying became organized, and aeroplanes patrolled in larger and larger formations and in layers, each unit being allotted its respective duties, signals being made by coloured lights. Slower aeroplanes were escorted by fast fighters; other fighters, like hawks, moved on mobile offensive patrols.

As peace seemed no nearer in 1917, redoubled efforts were made in the air. America joined in, and American fliers joined British squadrons, finally forming their own; the Italians had developed large, very high and very capable fighters; the Austrians, the Turks, all realized what air-power meant. The British used large twin-engined flying-boats against the submarine. The Germans eventually attacked with big float-seaplanes of remarkable speed. Scouts were flown off lighters at sea against airships, and off the decks of battleships and "mother" ships. Formation flying was developed and aerial fighting of the fiercest intensity was the prelude to every big land operation. The British SE5A's and Sopwiths, developed the French Nieuports and Spads, the German Albatrosses, Roland and Fokkers, swept the sky in "circuses" 30 strong, and the effect of superiority of performance was hard to distinguish from sheer skill in handling.

As the last and bitterest struggles of the World War were being waged in 1918, aerial activity reached its zenith. The deep hum of aircraft practically never ceased by night or day, in fair weather or foul. Large twin-engined Handley Pages and German Gothas flew farther and farther afield on bomb raids; retreating armies in the East fled before the onrush of death from the air. Aeroplanes flew low and attacked anything they could find on the ground. Large flying-boats patrolled vast expanses of water. The night was full of the attackers and the attacked, for fighting scouts had learnt to seek out and fight the night bomber. Engines had become more and more powerful and had reached 400 horse-power. The height at which an aeroplane could fly was limited rather by the physical endurance of the pilot, even with the help of oxygen, than the possible "ceiling" of the aeroplane. It would hardly be an exaggeration to say of the aeroplanes used in the first and last phases of the World War that their relative effectiveness as fighting implements was commensurate with that of a bow and arrow and a modern rifle.
The Art of Flying in War.—If, in war, higher performance was the prime means of gaining the position to strike, controllability was essential to direct the blow. Pégoud had given a glimpse of the possibilities of aerobatics in 1913, and during the war these possibilities were explored to the uttermost. Probably owing to temperament, the French led the way. The pilot of a fighting aeroplane simply came to regard his machine as a mobile gun platform, whose motion must be in sympathy with his lightest touch to enable him to get his sights on the target. In fighting-scouts the guns were integral with the aeroplane, the nose of which was controlled so as to point them at the target. With opposing machines of equal performance the striking position had to be gained by manoeuvre, confidence in which was inspired by a good view of the opponent. In order to use his guns effectively, the pilot's area of view had therefore to be made as large as possible. Though “looping” itself was little used, half-loops and “Immelmann” turns enabled the pilot to turn rapidly while gaining height.

**Fig. 5.—Immelmann Turn.**

Until 1916 spinning nose-dives had merely been associated with loss of flying speed and control, almost always with fatal results. A courageous demonstration of the method of recovery from a spin by Goolden, and later the practical application of the theory by Lindemann, both at the Royal Aircraft factory, did much to prevent future accidents. A spin came to be regarded, not with fear, but as a means, if crippled, of eluding attack. French pilots again pointed the way in the art of “rolling,” a manoeuvre in which the aeroplane is rolled about its longitudinal axis. In 1917 this manoeuvre was widely practised. The development of an aerial combat was so swift that the first few seconds might decide the fate of one of the opponents. It was rather in a brilliant combination of the manoeuvres described above, calculated to make effective striking possible while presenting an elusive target, than in the use of any single manoeuvre, that the war pilot put his trust. He had to study the characteristics of the aeroplane he was attacking, single or two-seater or large bomber, gauge its weakness, divine the mentality of its pilot and pit his skill against it; but it was grit and the will to close and finish it that alone could be the decisive factor.

To make possible the achievements of the fighting pilots, and to solve aerodynamic problems continuous experiments with new engines were carried on behind the scenes. High performance and controllability were not achieved without the incessant labour of scientists and designers, who were not a little baffled by the conflicting and rapidly changing demands often expressed with emphasis rather than illuminating precision; by the time new features in design could be given air trial the original demand had changed out of recognition.

And for military requirements something more than controllability was required; for besides having to control the aeroplane the pilot had to examine maps, operate wireless, watch many instruments, navigate, care for his guns, and keep a perfect look-out. If the controls were temporarily released the aeroplane ought in some measure to look after itself; in other words, be stable. In 1914 the BE2, and later the FE2, aeroplanes were altered so as to be stable longitudinally in partial conformity with Bush's RE1 design. They were thereupon called BE2C and FE2B; with these the flyer's hands were free, and with them no less than seven airships were brought down, a result no doubt assisted by the confidence which stability inspired in night flying. But it then seemed that stability impaired controllability. By 1916 so strongly did war pilots desire the maximum of control that for some time many looked upon stability with disfavour. Gradually, however, a neutral stability was found to be compatible with the desired control. An added safety was that stable aeroplanes would automatically tend to recover from a spin after loss of control, and that unlike unstable aeroplanes, they would tend to return to a normal attitude if they became inverted unintentionally or during the course of violent manoeuvres. Great as was this advance in aerodynamic knowledge, problems equally great remain, the solution of which can only be reached by constant and arduous experiment.

The Return to Peace.—Civil aviation was mainly restarted by the conversion of war types, which were not so well suited as if designed for the purpose. Specialization of type commenced in two directions; aeroplanes destined for travel and transport and those designed for racing.

The year 1919 saw wonders as great as any that had gone before. On June 14th-15th Alcock crossed the Atlantic on a Vickers-Vimy with twin Rolls engines in 16 hours 12 minutes, by which he won the Daily Mail £50,000 prize, and for which he was knighted. Of Hawker's plucky attempt and descent into mid-Atlantic; of Alcock's battle with driving mist, cloud and darkness; of the navigation of Whitten Brown, his companion; above all, of the human endurance underlying the feat, it is impossible to speak in measured terms. Just prior to Alcock's achievement there was one of a different kind, a triumph of organization for the Admiralty, which, for Lt. Cartwright and for Lt. Casey, by means of a BE2C “busky,” gained the passage of 150 m. under power on a rough sea, in the flying-boat NC4. In the late autumn Ross-Smith and his brother flew another Vickers-Vimy to Australia in 28 days, won the £5,000 offered by the Australian Government, and were both knighted.

High-powered racing aeroplanes again appeared. Janello, in an Italian seaplane, put up a fine performance for the Schneider Cup at Bournemouth at a speed estimated at 150 m.p.h., but, though virtual winner, had unfortunately to be disqualified. Gathergood won the Aero Club Derby at 129 m.p.h. on a De Haviland aeroplane. Racing machines reached speeds of 170 and 180 m.p.h., and climbs were made to over 30,000 feet.

In 1920 Van Ryneveld flew from England to Cairo, and thence after many adventures to the Cape. He crashed two aeroplanes on the way, and arrived at his destination on a third supplied by the South African Government; but considering the conditions for flying in Central Africa his achievement is of the first rank.

The Schneider Cup and the Gordon Bennett, two classic races, were won respectively for Italy by Lt. Bologna in a Savoia seaplane at Venice with an average speed of 160 m.p.h., and by Sadi Lecointe at Étaples at 166 m. per hour. Courtney won the fifth Aerial Derby in a Martinsyde racer with an average speed of 153 m. per hour. At Étaples the Farman "Goliath," a large passenger machine, remained aloft for 24 hours 19 minutes, beating all duration records. In America Maj. Schroeder on a Le Père biplane with a supercharged engine reached a height of 35,000 feet. The fast American and French racers continually raised the speed record, until Sadi Lecointe on a Nieuport reached 313 k. per hour over a measured kilometre. By the end of 1920 racing machines had reached a speed of nearly 200 m.p.h., a military type scout had climbed to 20,000 ft. In 15 minutes, a large commercial machine had climbed to 12,000 ft., with a weight equivalent to 26 passengers, fliers had climbed over six miles into the air, and an aeroplane had remained aloft for over 24 hours.

To promote safety, experiments were carried out to reduce landing-speed while retaining a reasonable top speed by means of wings variable in flight, a problem to the solution of which Handley Page offered a notable contribution. In spite of these and other difficulties so little risk now remains that the number of miles flown for every accident is something like 35,000, or one-and-a-half times round the world.

The years from 1909 to 1920 reveal a story of progress that, even allowing for the extraordinary stimulus of the World War,
is surely without parallel in the annals of engineering. And in this story may be found the hint of a tremendous future.

II. DEVELOPMENT OF AEROPLANE DESIGN

Design of Lifting Surfaces.—The determination of the forces acting upon a body moving through a viscous fluid, such as the atmosphere, is a problem so far not amenable to mathematical solution, and design must therefore be based upon experiment. A vast mass of experimental data has been obtained by testing models in wind tunnels (by Eiffel in Paris, by Prandtl at Göttingen, at the National Physical and other laboratories) and by experiments with full-sized aeroplanes, principally in England at the Royal Aircraft Establishment, Farnborough. A very useful amount of information had been acquired before the war, but this has been greatly extended during the war period.

Lifting-surfaces of various shapes have been used in the design of aeroplanes, disposed in a variety of ways. It was immediately evident that the span or spread of the wing across the line of flight should be large in comparison with the "chord" or dimension along the flight path. The ratio of the span to the chord has been termed the "aspect ratio." Aerodynamic efficiency increases with increasing aspect ratio; but it is desirable to limit the aspect ratio for constructional reasons and also in order to reduce the room required for housing. The greater aerodynamic efficiency, moreover, becomes neutralized after a point by the head resistance due to the additional external bracing required. A compromise must be made, and the average figure used is in the region of six to one. It was also evident that the wings should be cambered along the line of flight. The early aeroplane wings had approximately the same curvature of upper and lower surfaces. Wind-tunnel experiments, however, showed that the curvature of the upper surface had but small influence compared with that of the upper surface, a result which enabled the designer to increase the thickness and internal strength of the wings and reduce external bracing.

Extensive wind-tunnel research has been carried out to find the best cross-section shape of wings. Greater lift can be obtained from highly cambered wings, but thinner wings offer less resistance to motion at small angles. An aeroplane should have as large a speed range as possible. While a wing of high-lifting-capacity is required to fly slow, small resistance is required for fast flying, that is at small angles of attack. A greater speed range is obtained by the use of wings of small curvature (about r in 15), the same lower limit being attained by the use of a larger area to carry a given weight. Wind-tunnel experiments further determined the extent to which the curvature should be greater towards the leading edge of the wing.

Early writers sometimes stated the requirements of a wing as consisting purely of a high ratio of lift to resistance at some angle of attack. The requirements are in reality more complex. To secure a wide range of speed a high ratio of lift to resistance is required at high angles (due in comparison with the angle at which the wing attains its greatest lift at a given speed) and in addition at high values; this ratio is required at the intermediate angle at which the aeroplane climbs. This is not all. For longitudinal stability the travel of the centre of pressure when the angle of attack varies should be small, as this travel on a curved surface produces instability. The wing section best meeting all these requirements is probably the British Royal Aircraft Factory's No. 15, designed early in 1916.

The resistance of a wing must, however, be considered in relation to the resistance of the external bracing attendant upon its use. It has been suggested that the thick wing, in spite of greater head resistance due to the wing, might prove superior by making possible the suppression of all external bracing, and the German Junker and others have designed aeroplanes on these lines.

The term "wing" is commonly used of the half of a lifting-surface on one side of the aeroplane, the whole surface constituting a "plane." Thus a monoplane has one pair of wings. A tandem aeroplane has two or more pairs of wings arranged as the name implies. The terms "biplane," "triplane," "quadruplane," denote that two, three, or four planes are superposed. Langley's "aerodrome" is an early example of the tandem aeroplane. This type is inconvenient structurally and aerodynamically very inefficient. The rear plane acts upon which a downward tread has been imparted by the plane in front. The reaction upon the rear plane is therefore inclined backward by the angle through which the air has been "downwashed" by the leading plane. In multiplane systems in which the planes are placed one above the other, each plane operates in air whose motion is influenced by the others, and the ratio of resistance to lift is less than the ratio which each would experience if acting alone. If, however, the planes are placed at a sufficient distance apart, so that the gap between is roughly equal to the chord of the planes, the mutual interference produces an effect comparable with that due to a reduction in aspect ratio such as is found necessary in the design of a monoplane. Using the same aspect ratio a given area is disposed in a biplane in half the span required in a monoplane. The biplane forms a good structure, the planes forming the flanges of a box girder. In the monoplane the bracing wires make small angles with the planes, with consequent high tension in the wires and high compression in the spars of the wing. In the biplane the wires make obtuse angles with the planes. In reviewing the examples of the two types, it is found that the monoplanes are relatively of heavy wing loading and low aspect ratio. In the triplane the upper and lower planes may form the flanges of the girder, or the structure may consist of two girders superposed. This does not possess the same structural superiority over the biplane, as does the latter over the monoplane. The triplane arrangement provides a means of reducing span by increasing height. An early example of the triplane is that designed and flown by A. V. Roe in 1909. A Sopwith triplane was used by the British army during the war. The type may be suitable to large aeroplanes, in which reduction of the weight of the structure and of bulk is especially needed.

The great majority of aeroplanes have been of the monoplane and the biplane types, the latter predominating since 1912. The first aeroplanes to fly were biplanes and by far the larger number of aeroplanes in use to-day are of this type. The monoplane appeared about the opening date of the period under
AERONAUTICS

FIG. 7.—Early Wright Aeroplane. (Propeller Biplane.) (Elevators in Front; Rudder in Rear.)

FIG. 7b.—Early Blériot Aeroplane. (Tractor Monoplane.) (Elevators and Rudder in Rear.)

signed "tractor" biplanes. During the war the monoplane was more largely used by the French and the Germans than by the British. The names most associated with the monoplane are French: Blériot, Morane, Nieuport. The "Fokker" monoplanes used by the Germans take their name from a Dutch designer probably inspired by the French designs. During the years 1914-8, the biplane was in the ascendant, but the monoplane was afterwards revived in the form of the aeroplane with thick "cantilever" wings without external bracing. The monoplane appears to be a type convenient in small sizes, but unsuited for the larger aeroplanes.

Position of the Airscrew.—Airscrews have been described as "tractor" or "propeller" according as the airscrew shaft is placed in tension or in compression by the thrust, and corresponding aeroplanes are usually called by the same names. The first biplanes, those of the Wrights and the Farmans, were of the "propeller" type, colloquially "pushers"; almost all monoplanes were "tractors."

In the tractor, monoplane or biplane, the order of disposition of the component parts is generally from front to rear: airscrew, engine, crew; and the body is prolonged to carry stabilizing and controlling surfaces at the rear. In the pusher the order is reversed and the controlling surfaces are carried on an open frame ("outrigger") in front, at the rear, or in both positions.

On a "pusher" the field of view forward is superior, and great stress was laid upon this by the British War Office after the military trials in 1912. The necessity of aerial fighting was proved in 1914, and the tractor was found unsuitable owing to the obstruction in the most effective direction for firing. Pushers were therefore ordered for fighting, at first carrying pilot and gunner, and later carrying only one man with a machine-gun fixed in the aeroplane. The situation was completely altered by the device of firing through the airscrew-disc. The blades were at first protected by deflector plates, but shortly after mechanism was used to time the fire between them, the invention of Constantinescu, a Rumanian. The aeroplane was directed bodily at the target. The "tractor" then replaced the "pusher" fighting aeroplane; but "propeller" airscrews continued to be used on seaplanes, on aeroplanes for night duty against Zeppelins, and on large twin-engine aeroplanes.

discussion, and on an aeroplane of this type Blériot crossed the Channel in July 1909. It was more cleanly designed than the biplane of that date and was regarded as the faster type. It was largely used for trick flying, and figured ever more widely in aeronautical exhibitions. At the outset of the war it had still a reputation for speed, but had found a rival in the better de-
The "tractor" is the more convenient design, slightly better aerodynamically and reputed safer in a "crash."

**FIG. 9.—Propeller Biplane of 1914-16.**

**Weight and Head Resistance.**—The aeroplane designer is continually interested in the relative importance of weight and head resistance. At the start attention was naturally concentrated upon the production of a light structure. Knowledge of the resistance to motion of bodies of various shapes was meagre and was most probably gauged in the mind of the designer by the frontal area exposed, irrespective of shape. It was not realized that a strut of circular section offers twelve times the resistance of a struts of the best "streamline" or "fair" shape of the same frontal area. The light biplane structure of the Wrights and the Farman contained a network of struts and wires offering a very high resistance. To reduce resistance, exposed parts may be "faired," which involves adding weight; and the number of external parts may be reduced, which again increases the weight of the structure. Wrights and Farman may be contrasted with the fast monoplanes and biplanes, the latter employing only a single bay of struts on either side, and finally with the unbraced monoplanes of Junker and Fokker.

"Streamline" wires were first designed for the British army dirigible "Beta" in 1912, and fairshaped wires were in 1914 fitted to aeroplanes designed at the Royal Aircraft Factory. They have since become the most usual bracing of British aeroplanes. They offer approximately one-eighth of the resistance of cable of the same tensile strength. Their metallurgy required careful study, and hence in other countries cable has continued to be used, frequently duplicated, the cables lying one behind the other with a wood "fairing" between them. Struts of streamline shape were in use at an earlier date. The bodies of aeroplanes have improved in form, the crew has been protected from wind pressure, and the spokes of wheels have been covered in fabric.

The drag of a biplane of moderate speed is made up roughly as follows:

<table>
<thead>
<tr>
<th>Part</th>
<th>Percentage</th>
</tr>
</thead>
<tbody>
<tr>
<td>Main planes</td>
<td>30%</td>
</tr>
<tr>
<td>Bracing of main planes</td>
<td>20%</td>
</tr>
<tr>
<td>Body</td>
<td>30%</td>
</tr>
<tr>
<td>Undercarriage</td>
<td>15%</td>
</tr>
<tr>
<td>Tail surfaces</td>
<td>5%</td>
</tr>
</tbody>
</table>

These figures show the importance of careful design of all parts. Much of the resistance of the wing-bracing occurs at the joints of wires and struts to the planes, and the resistance of the body is largely due to the necessity of cooling the engine, either by water radiator or by flow of air over the cylinders.

The weight of the complete structure, excluding the power unit, fuel, crew and other load borne, is about one-third of the whole weight of the aeroplane, but varies with the total weight, with the weight carried per unit of area of lifting surface, and with the strength of the structure. The following figures are averages for a number of British aeroplanes:

<table>
<thead>
<tr>
<th>Load borne per unit area</th>
<th>6</th>
<th>10</th>
<th>6</th>
<th>10</th>
</tr>
</thead>
<tbody>
<tr>
<td>Load factor</td>
<td>4.8</td>
<td>4.8</td>
<td>4.8</td>
<td>4.8</td>
</tr>
<tr>
<td>Structure weight of % of total weight</td>
<td>28%</td>
<td>25%</td>
<td>27%</td>
<td>24%</td>
</tr>
</tbody>
</table>

The "load factor" is the number of times the weight of the craft, which the wings will support, a measure of the strength.

Using one of the light engines now available, the power unit to give a speed of 100 m. an hour will weigh about one-quarter of the total, leaving 40 to 45% for fuel, crew and cargo.

Wing Loading and Horse-Power.—The lift of a wing is proportional to its surface, the atmospheric density, the square of the speed and the angle at which it meets the air measured from the angle giving no lift and up to an angle near that known as the "critical angle." At this angle the lift is a maximum (if the other factors be supposed constant) and above it the lift decreases. The wing in passing through this angle is said to be "stalled." Stalling occurs when flying as slowly as possible. After stalling it is no longer possible to increase the lift by depressing the tail of the aeroplane and it is necessary to dive in order to recover flying speed. This has been a frequent cause of accidents when flying too low to have room for a dive. Moreover, the wings when stalled have lost their normal tendency to oppose rotation about the line of flight and now tend to "auto-rotate" or act as a windmill. The aeroplane may therefore drop one wing and pass into a steep spiral glide known as a "spinning nose-dive," from which it may be brought to normal flight by the same diving process reducing the angle of attack of the wings. There is no danger in the stall or the spin so long as there is space for the recovery and knowledge of the action required.

**FIG. 10.—Curve showing lowest speed of flight possible with given wing-loading and the usual thin wings.**

Wing-loading, the weight borne per unit area of sustaining surface, determines the speed at which the wings become stalled and therefore the slowest alighting speed. With constant loading, as the speed of aeroplanes increases, wings attack the air at ever finer angles, very soon passing the angle of lowest resistance for a given lift. To increase speed it therefore becomes desirable to increase the loading, or in other words to reduce the area of the wings. This reduction has also the merit that it reduces the bulk of the craft, the resistance of external bracing and the weight of the wing structure. To attain the greatest height heavy wing-loading is not required, and the best loading for a high ceiling would to-day be considered a light loading.

For fighting, power of rapid manoeuvre is essential. The aeroplane of light loading can be turned in a smaller circle. The total weight is, however, approximately fixed by military considerations, and light loading implies large wing area and consequent greater resistance to angular acceleration, so that the lightly loaded aeroplane cannot so quickly be "banked" to the correct angle for the turn. Given the wing area, the aeroplane having the lighter loading is the more manoeuvrable; given the weight, the heavier loaded aeroplane is at least the equal of the other: Aeroplanes carry a larger area of sustaining surface than they require, except for alighting, and it is the
difficulty of bringing the aeroplane to land at high speeds which prevents the increase of loading beyond 10 lb. to the square foot.

In commercial use, economy dictates an increase of loading; safety demands that the aeroplane may alight at speeds and in a space impossible with high loading. Attempts have been made to make the wing area or the wing shape variable in order to reduce the lowest speed of flight, while retaining the other advantages of heavy loading. None has so far been successful.

The largest engines developed were insufficient for the larger aeroplanes, into which two engines were commonly built, and in some cases four or more.

Two separate power units have been regarded as conducive to safety. Experience has so far not confirmed this. It is essential that the power of one engine alone should be sufficient to fly the aeroplane, and the twin-engine aeroplanes used during the war were not all provided with so large a total power. Again, the engines were carried on either side of the centre and the line of thrust of each offset by a considerable amount. This introduced difficulties of control, because rudders were unable to balance the offset line of thrust at the low speed at which the aeroplane could be flown level on one engine only, and there was danger in the event of sudden failure of one engine near the ground.

The table gives some particulars of a few typical aeroplanes through the period under review. The figures are approximate:

The horse-power and speed given above are uncertain.

The Large Aeroplane.—For the same aerodynamic performance, the lifting-surface of an aeroplane must be propor-
tional to the weight. If aeroplanes of all sizes were constructed of the same materials and geometrically similar in all parts, the weight of the structure would increase with increasing size as the cube of the linear dimensions, that is, as the $3/2$ power of the total weight. This does not in fact obtain, because geometric similarity would give greater strength to the larger aeroplane; also the design may be elaborated and materials worked with greater freedom and dimensions to some aeroplanes are not designed to have the same strength as smaller craft, as they are less sharply manoeuvred. Nevertheless, the weight of the structure is to be expected and is in fact found to become a larger proportion of the total weight as the size increases. It is therefore disadvantageous to increase size indefinitely and there is in fact a best size depending upon the duty to be done.

To carry an indivisible unit of cargo, such as a large bomb, an aeroplane of at least a certain size is required; hence we find size increasing. Sometimes it is preferable to carry a total load in a smaller number of larger aeroplanes, because the weight of the crew becomes less in proportion to the cargo carried, so that every square foot of wing and every unit of engine power of a fleet carries more useful load. Initial outlay and fuel consumption are reduced and there is further an economy of pilots. At some point the larger aeroplane requires a larger crew, and for war the larger "bomber" must carry a number of gunners and offensive armament for defence against more mobile attackers. The optimum size for a commercial service with a sufficient volume of traffic is what would be termed to-day a large aeroplane (say 7,000 lb. at least). The actual size depends to some extent upon the speed of the service, which governs the relative costs of fuel and personnel, and also upon the distances.

The first large aeroplane flown was the Russian Sykorsky in 1913. Large aeroplanes were demanded in 1915 for bombing and were increasingly used during the war. The Handley Page (13,000 lb. gross) was extensively used by the British. The "Gotha" and others were used for raids on London. The same Handley Page aeroplanes and a subsequent design were employed on a passenger service between London and Paris throughout 1919 and 1920. The "Vimy" (12,500 lb. gross) crossed the Atlantic, flew from Cairo to the Cape, and from Europe to Australia, and has been used on a London-Paris commercial service.

Controlling Surfaces.—Stability in aviation is discussed in Section 111. Complete inherent stability is obtainable by a proper distribution of weight and subsidiary surfaces and suitable arrangement of the main planes. The planes are commonly inclined upwards from front to rear to secure a righting couple if one wing tip fails and the aeroplane begins to sideslip. A vertical surface at the rear, known as a fin, is general although the rudder may entirely replace this surface. The angle of the "centre of gravity" of the wings is an important factor as regards instantability, and a subsidiary horizontal surface is required either in front or in the rear. To secure an "longitudinal" stability, the centre of gravity must be sufficiently forward in relation to the main planes, and the load on the subsidiary surface maintains equilibrium. The aeroplane has three degrees of angular freedom and has almost invariably employed three means of control: elevators, to produce a "pitching" motion, and so govern the angle of attack of the wings and the speed of flight; rudders to produce motion about the vertical axis; and warp or ailerons, to secure lateral balance and adjust the angle of "bank." The early Voisin aeroplanes were thus provided for lateral control. The aileron system has a natural tendency to bank, which is accentuated or reduced by sideslip onwards and inwards respectively if the wings are inclined upwards from front to tip or fitted with a vertical surface along the centre of gravity. The Voisin aeroplane carried curtains between the planes to provide this righting couple and was sufficiently controllable for the requirements of the pioneer content to achieve flight. "Lateral" control is desirable and is clearly necessary for regular flight. The Wright aeroplane was provided with "warping" the wings, and this method was extensively used up to the end of 1914. Control has been more generally obtained by means of ailerons. The principle of the Wrights' aileron is that the leading edge of the wings at the tips. Elevators have been placed both in front and in the rear: rudder always in the rear. They have constituted the whole, or only a part, of the necessary stabilizing surfaces. Control with a single rudder requires a very large "knee" surface, which is adequately provided by the body of the aeroplane and the exposed struts of the structure. The tendency of design towards the "tractor" type places elevators and rudders most conveniently at the rear end, and this gives a clear field of view forwards. The early biplanes with an elevator in front and rudder at the rear disappeared about 1914: the monoplanes conformed to the modern usage. Both elevators and rudders are usually hinged portions of fixed surfaces, but in some cases the entire surface has been movable and constituted the elevator or rudder. The latter arrangement has not provided stability if the controls were abandoned. Later the fixed horizontal surface was made adjustable by the pilot during flight and known as a "trimming tail plane," a device much used by the British from 1916 onwards. It enabled the pilot to vary the speed of flight at which no pressure upon the controlling lever was required, and effectively increased the range of control resulting from the application of a definite force.

The arrangement of control levers or wheels, at first very diverse, became standardized in 1915-6, and consists of a "rudder bar" operated by the feet and a hand lever whose fore-and-aft movement operates the elevators and whose lateral movement provides lateral control. The rudder bar and the lever are moved in the direction in which it is desired to move the aeroplane. In larger aeroplanes rotation of a wheel mounted on the fore-and-aft lever actuates the ailerons, the fore-and-aft control remaining as before. The lever or wheel is generally connected to the control surfaces by steel cables, although shafts in torsion and compression members have also been used.

Balanced control surfaces, although in use from an early date, only became necessary as the size of aeroplanes increased. A part of the surface to be balanced is carried in front of the hinge and this surface is most frequently the rear portion of a fixed element, the part brought forward of the hinge being extended beyond the end of the fixed element. This so-called "horn" balance proves unsatisfactory. If a large "horn" were used (adequate to give ease in normal flight), there was overbalance at low speeds, or when the aeroplane skidded, and the controls would then tend to "take charge." A more uniform effort results if the balancing projection is run the full span of the hinge, which must then be set back behind the fixed element. The front edge of the balanced surface is sharp and its movement takes place behind the bluish end of the fixed element. Alternatively separate balancing surfaces in advance of the hinge have been rigidly attached to the moving element and placed above the fixed element.

The imperfection of balancing obtained has led to the development of relay motors to reduce the effort. In these, power derived from the air by a small windmill is brought into play whenever the pilot attempts to move the controls. Relay motors had been but little used up to 1921.

Chassis or Undercarriage.—The Wright aeroplane alighted upon skins. It was launched by a catapult. The French pioneers took the air under their own power, and the Fabian and Bleriot used wheels. From 1909-14 combined wheels and skids were used. The wheels were commonly sprung by means of rubber cord. The skids might be brought into action if the alighting were imperfectly executed, and were carried well forward to prevent the aeroplane from turning over forwards when landing. Sometimes additional wheels were fitted in a forward position in place of the skins for this purpose. Under the tail a wheel was often fitted, but a small skid was used alternatively. Wing-tip wheels or more commonly light skids were used to protect the wing tips from contact with the ground. In Bleriot's
undercarriage the wheels were mounted as castors to facilitate landing across the wind. This was subsequently abandoned.

The common arrangement of undercarriage comprises a pair of wheels a little forward of the centre of gravity of the aeroplane and a small tail skid. The wheels, of wire-spoke construction with pneumatic tires, are attached to V-struts from the aeroplane by rubber cord. The tail skid is also sprung by means of rubber and is mounted on a swivel. Steering on the ground was improved in 1912 by arranging the tail skid to be moved by the rudder bar. The use of skids and wheels ahead of the main wheels was generally abandoned early in the war, except in the case of large aeroplanes.

Steel springs have been used, but rubber is superior to steel because it stores more energy for a given weight. Hysteresis in rubber is also much greater than in steel. To avoid bouncing after the first shock the energy received on impact should be restored as little as possible. This requirement led to the design of undercarriages containing a combination of steel spring and oil dashpot, such as the "Oleo" design fitted to the Breguet and to the Royal Aircraft Factory's "BE2" in 1914. This form of "shock absorber" was chiefly useful for night flying.

Methods of Construction.—The first experimenters built their aeroplanes of wood and fabric with metal at joints and in the form of piano-wire bracing. The aeroplane of to-day uses spruce for beams and struts and steel for joints and tension members, the latter in the form of stranded cable, or "rafwires," i.e., rods rolled into a coil and insulated and made of such material as steel, covered with linen, pulled taut by "doe," and varnished or painted for protection from sunlight and moisture. Frames composed entirely of metal were used as early as 1911, but wood remains in general use, except for the tropics. Steel tubes have been extensively used in parts, notably for the part of the body to which the engine is attached, for struts between the planes, and in the undercarriage. The use of steel tubes for the enginebearers gave place to wood owing to the greater absorption of vibration obtained.

The wings in the common type of biplane contain two wood spars of I or box section forming the flanges of a truss braced by wood or steel struts and cables or solid wires. To these spars are attached transverse ribs which give the shape of the wing and a light wood edge completes the frame. The linen covering is sewn on to this with a seam along the rear edge; stitched to every rib singly by means of a single or double row of stitches, the members and wire bracing. Bodies built of three-ply wood, with or without reinforcing members, have also been used. These retain their shape even when in an inflated state by being incompressible and perhaps some advantage against rifle fire; but the former have been preferred apparently as being more easily repaired and inspected and allowing of a more certain calculation of stresses.

Metal construction advanced further in Germany than in other countries. Junker produced aeroplanes without external bracing strength being obtained by the use of thick wings. These contained in place of the usual two spars a number of steel tubes interconnected by tubes forming triangles. The wings were covered with aluminium sheet corrugated so that the air flowed along the corrugations. The interconnecting tubes and the corrugations replaced the usual ribs. Great Britain has experimented with spars and ribs of steel and duralumin, and secured the necessary strength without increase of weight; but metal construction is still in the experimental stage. The principal difficulty in the use of steel lies in the prevention of local buckling due to the thin gauge of metal required to secure a light structure. Welding is unreliable owing to the impossibility of detecting weakness in the finished part, and joints are made by rivets or bolts. The spars have been made of duralumin on the same lines, though built of thoroughly well seasoned wood.

The Strength Required in the Structure.—The aeroplane structure is subjected to a very variable load. In straight flight the wings are subject to a weight of the aeroplane (with an "empty" weight, i.e., without the pilot and any other "payload") and to the air pressure. The wings must provide an accelerating force, depending upon the rate of turn and the speed of the flight. The pioneers were content to fly slowly, and the accelerations necessary when they dived were small. The larger variations in loads were due to gusts. They flew only in the calmest weather, but their speed was slow. As soon as the aeroplane was used for trick flying, the effect of gusts became relatively insignificant, and the accelerations due to manoeuvres became the necessary basis of design. In an aerial combat the wings may have to sustain the weight of the pilot and of other load, and to prevent "flying" the aircraft for the accelerations which could be produced by flattening out too rapidly from a steep dive, in which a speed of over 200 m. an hour may be reached.

The determination of the load required to an aeroplane is a part of the problem of specifying the strength required of the wing structure. We must also know how this load is distributed over the surface, along and across the wing, and in the load or rather the speed of flight. The method by which the "centre of pressure" on the wing. As the angle between the wing and the direction of motion decreases the centre of pressure moves forward with the wing, and it is at an angle of attack that in a nearly vertical dive at high speed, although the lift of the wings is small, there is a large couple acting upon them tending to twist them and to turn the aeroplane over on its back; this is resisted by the action of the tail. A number of accidents of early accidents occurred in the course of a "col piqué," or steep dive.

Rough calculations were probably made of the strength of the early aeroplanes, and in 1912-13 those supplied to the Government were tested by inverting them and loading the wings with sand. Spars of wings were also tested separately, but as a rule the strength required and the strength realized were uncertain quantities in the number of accidents to monoplanes led to this type becoming suspect. Early in 1912 Blériot forwarded a suggested explanation to the French War Office, which resulted in the suspension for a few months of the use of monoplanes by the French army. Later in the year a committee was appointed in England by the War Office, although the navy continued to use them. A committee was appointed and reported early in 1913. It decided that the accidents were due to the construction of these monoplanes, and that if anything could be done to improve the strength of those wings, they should be braced internally against drag (a remarkable omission previously), the main bracing wires would be required to be made of the fabric well fastened to the ribs, especially on the upper surface. There were to supply evidence of strength; official inspection and investigation of accidents were instituted; and the question of stability and the danger of the "col piqué" and recovery were to be investigated.

Prior to this, efforts had been made in England to impose a factor of strength based on the load in straight level flight through steady air. The first such factor was suggested by the Advisory Committee of Aeronautics, which reported in 1914 that the British Advisory Committee for Aeronautics issued a report on "factors of safety," regarding the load factor as the product of two factors, one representing the number of times the maximum load might exceed the normal load, and the other a factor to cover possible faults of material and workmanship. The first factor is based on the load due to a banked turn combined with a gust, and to the load from the load variation possible, and this is a factor of 1.35. There is no record of the obligatory use of such factors in France or Germany at this date.

During the war the problems involved were investigated both mathematically and experimentally, and for the front a factor of 1.4 was carried out on the Royal Aircraft Factory by aeroplanes fitted with an accelerometer and with tension meters on the wires. The distribution of pressure over wings has been measured in wind tunnels (first by Edelf in Paris) and on aeroplanes in flight at Farnborough. It is now possible to specify the strength of the various members of an aeroplane with sufficient accuracy for any manoeuvres required. The "load factor" demanded has never risen to 12, but now ranges from 4 to 8, the lower factor for the large aeroplane which is not so violently manoeuvred. The adequacy of these factors has been confirmed by experience.

The need for extreme lightness precludes the use of the factors of safety currently used in other branches of engineering, and instead accuracy of stress calculation and careful inspection and testing of materials are imposed. It became the practice of the British Government to equip aircraft with an "analysis" in detail by a committee or by a company and with a proof load on one aeroplane of a type. Other governments followed. Since 1918 all Great Britain aircraft have been certified to a load factor of 4, and a type may be used for commercial purposes. Drawings are submitted by the applicant from which calculations of stresses are made by the Air Ministry.

The calculation of stresses proceeds upon the usual lines, common to other branches of engineering, but with rather greater accuracy of detail. The theorem of Three Moments is applied to the spar, which require treatment as beam continuous through a number of supports and subjected to end load. Buckling and torsion practice has somewhat extended this theorem. A theory of the strength of struts of tapering section has been evolved. Knowledge of the mechanical properties of timber has been much extended.
The Airscrew.—The Rankine-Froude theorems on propulsion by the streamlined projection of a stream of the atmosphere through the use of a screw-propeller, or other means, are well known. These state that the highest efficiency is attained by the projection of the greatest amount of fluid at the lowest speed, and indicate the use of propellers of the greatest practicable diameter. The thrust, considered is the kinetic energy imparted to the fluid. An upper limit of efficiency is thus determined in terms of the diameter and the thrust of the screws used. In practice, the performance of marine screws proceeds mainly upon empirical lines based upon experience. The early airscrews were designed by a similar process of trial and error.

W. Lancaster (Aerodynamics, 1892), regarding the airscrew as a twisted aeroplane wing rotating about one tip as it advances through the air, assumed that the total reaction may be obtained by integrating the forces acting along the radius of the section. If these were elements of a complete wing. This method of treatment, which was also advanced by Drzewiecki, has provided the basis of airscrew design. As first advanced, the theory was incomplete, chiefly because it ignored the fact that the blades in following each other act on disturbed air. For example, if the number of blades be increased, the theory indicates no fall in the efficiency, and reactions directly proportional to the number of blades, which experiment showed to be untrue. Moreover, the efficiency so calculated might exceed that given by the Rankine-Froude theorems. It was therefore sought to combine the two aspects of the advance of the airscrew, the wing theory, and the futility theory. The combined theory leads to two important conclusions, completely verified by experience.

Firstly, the efficiency increases with increasing ratio of the pitch at which the screw operates to its diameter up to an optimum value. Secondly, with increase of the thrust and speed the diameter must be so large that it acts upon a sufficient mass of air per unit of time to attain a satisfactory efficiency. The latter brings the theory into conformity with the law of Rankine and Froude. The former in practice brings the airscrew designer into conflict with the designer of aeroplane motors. Higher Cranshaft speeds are required to produce a light-weight internal combustion engine capable of developing the power required to drive high airscrews. This has resulted in a large number of aeroplane engines being arranged to drive the airscrew through a reduction gear. The point at which gearing becomes desirable in practice has not easily been determined upon a sure basis. Among these are a small loss of energy in the gears, added weight and cost, various practical reasons for dispensing with additional components, and the necessity for avoiding the stress and strain effects of the greater torque of the slower running airscrew upon the control of the aeroplane, which must be offset against the gain in airscrew efficiency. In this question is also involved the consideration of the strength of the airscrew to resist the stresses due to rotation. This imposes a limit upon diameter, decreasing as the speed of rotation is increased, which may result in a further reduction of efficiency for the high-speed airscrew.

During the early years of the aeronautical industry, airscrews were built for which single engines of the required power were not available. In so far as two engines were sufficient, these were placed on either side of the main body of the aeroplane. Thence an airscrew is provided for each engine necessary to install four engines in a few aeroplanes and these were placed in pairs driving two pairs of airscrews in tandem. The design of the rear propeller in this arrangement involves an estimation of the effect of the airscrew on the front. With the same limitation of diameter the efficiency of propulsion attainable is approximately the same as if the two engines were coupled and drove a single airscrew of the same diameter, but is limited by the necessity of a clear separation of the airscrews in front. The tandem system is preferred for reasons of compactness and the difficulties of control attendant upon the use of a number of airscrews.

The propeller, unlike the propeller of ship or airship, is required to transmit the full power of the engine at different speeds of flight, both when the craft is flying level at full speed, and when it is climbing or descending in the vertical or any other plane. It is, therefore, necessary to discharge both functions in the most efficient manner possible in each case. This was of little consequence in the early days of flight when the range of flying speed was small; but as the range was increased, some attention was paid to the design of airscrews of variable pitch. These have been experimented with, notably at the Royal Aircraft Establishment, with some success, but they have not been used so far in service. If any device for preventing the loss of engine power with increasing height by an initial compression of the charge to ground-level density should come into use, the variable airscrews might become indispensable. Such devices arc, however, still in an experimental stage.

The number of blades in an airscrew is commonly two, but four blades have been extensively used. The four-bladed airscrew has an advantage in convenience for storing and transport. The use of more blades reduces vibration due to errors in blade angles, and eliminates gyroscopic vibration when the aeroplane is turning, and vibration due to aerodynamic causes when the axis of rotation is inclined to the line of flight and when the aeroplane is turning. Airscrews have been almost universally made of timber, which should be continuous through the slot from blade tip to blade tip. This has prevented the use of three blades. In deciding the number of blades, two or four, the designer is largely guided by the blade area required, which depends upon the speed of motion of the blade and the power transmitted. Thus a low-speed airscrew has a large number of blades, whereas for a high-speed two blades are preferred. A four-bladed high-speed screw might require such narrow blades that in order to resist the bending due to the thrust they would be so thick as to reduce the efficiency seriously.

At the speed of flight of an aeroplane the changes of pressure of the air flowing past the wings amount only to a small fraction of the pressure of the atmosphere. All the blade tips of airscrews, however, commonly reach speeds of 500 ft. per second, approaching the velocity of sound in air. It follows that while the wings may be regarded as operating in a fluid of constant density, the compressibility of the airscrew may be neglected. With increase of blade tips, the blade tips must be designed to drive the airscrews as the speed of the blade tips was increased. The error cannot, however, be ascribed to the effects of compressibility owing to uncertainty as to many other factors involved. On the other hand, the method of aerodynamic analysis led to sufficiently accurate design.

The screw-propeller as a mechanism for the transmission of power is convenient and efficient. In the airscrew narrowers, which can be used than in the marine propeller, and efficiencies as high as 85% have been attained with airscrews of high pitch and large diameter, smaller fast-running airscrews giving efficiencies of 75 per cent.

Fig. 15.—Variation of Thrust with constant Torque.

Owing to the light weight and high tensile strength of timber for its weight, the designer has found in wood his most convenient material. The designers in early years turned to the use of spruce and poplar, but have been criticized for the high stresses which were in the timber. The stresses are most severe. Honduras mahogany is satisfactory for most purposes. Santis and beech have also been used but are not satisfactory for higher powers and speeds. The screw is constructed of planks, or laminations, about an inch thick, glued together and cut to shape. The grain of the wood should be straight and run as far as possible along the blade. The method of construction secures maximum utilization of the strength of the wood by avoiding the large amount of large hysteresis and consequent power of damping vibrations. The Wright brothers' airscrews were made of spruce cut from a single piece of timber. An interesting design appeared in 1913, the 'Garden' airscrew, of laminated wood construction with the blades tilted forward so that to a large extent stresses due to rotation neutralized those due to thrust. The forward tilt was obtained by bending the laminations during manufacture, a rather questionable practice. This method of balancing stresses has not
been developed beyond carrying the most forward lamination to the tip of the blade and succeeding laminations to smaller radii, owing to the method of construction and the nature of the material used. It has been shown by experiment that this forward tilt renders the blade liable to twist under load.

The stresses in the blades have been calculated by crude methods which give an approximation to the stress along the grain. Fracture has, however, almost invariably occurred through the grain, in the thinner airfoils, by failure of the glued joints. Workshop practice has now so far improved that the strength of glued joints is equal to the strength of the blade itself. A recent report of the Airscrew Committee on aeronautical research has been added. The present knowledge of torsional stress in an aircrew blade led to the practical solution by G. R. Taylor and A. A. Griffith in 1916 of the problem of torsion of prisms of any section. The mathematical equations had already been stated, and the new development was the provision of an experimental method of solution. Theory can now indicate the shape of blade required to avoid twisting under the loads imposed in flight. Apart from the reduction of stress, this is of great value to the designer, who cannot with any certainty predict the performance of an aircrew if the blades twist in an unknown manner in flight.

In order to protect the blades from moisture the aircrew is varnished, or painted, and to protect against sand on land and spray on the sea, the tips have in some cases been sheathed in metal, but the practice of covering with fabric (dating from 1912-3) has recently found more favour. Japanese lacquer has also been used as a protective coating.

Several early aircrews (e.g. Breguet's) were entirely of metal, commonly aluminium blades bolted to a steel tube, a method only possible with the low powers and speeds of rotation of the early aircrew. Bodies of aircrew, Bleriot's, and later, have been made with a small, high-speed aluminium aircrew. Experiments with steel construction have proceeded slowly and steel may in time come into common use. Failure has been larger when the unrelatable nature of welding, and to brittle failures produced in the process. For production in moderate quantities, wood requires far less outlay. A modern development is the aircrew with detachable blades, so far in a purely experimental stage, the detachable blades of the aircrew have been imperfectly designed or the conditions of operation be altered, and of replacement of a damaged blade without renewing the whole. If the blades are of wood, shorter lengths of timber may be used, but it is more difficult to regard this as an inherent advantage of the system, because the difficulty of attaching wood blades to a centre are probably as great as the difficulty of making a satisfactory joint at the centre of an aircrew constructed entirely of wood.

An aircrew whose pitch is variable in flight is a particular case of the detachable blade screw, and the chief difficulty in the design of such a screw for high speeds of rotation is that of making the joint between the blades and the central shaft. In Britain and in America aircrews have been tested before use in flight by "spinning" by means of an electric motor. This test has been applied to new designs, to aircrews whose structure has been altered, but it is doubtful if this can be regarded as an inherent advantage of the system, because the difficulty of attaching wood blades to a centre are probably as great as the difficulty of making a satisfactory joint at the centre of an aircrew constructed entirely of wood. The practice was in force in this country in 1914 and has been continued. Flight conditions are not reproduced by the test, because the aircrew is not vanishing through the air, and because the crank- staff variation and vibration of the engine are absent. The thrust loading is more severe, the centrifugal loading less severe. Experience has, however, given considerable confidence in the test. In France the only test applied has been a loading of the blades to counteract the air forces, without rotation.

III. AERODYNAMICS

Experiments and Calculations on the Principles of Flight.—The recent history of the development of the aeronautical arts lies almost entirely upon experiments on aircraft and their parts. That branch of investigation which is least related to any other subdivision of engineering is the study of the forces which are experienced by a body when moving through the air. The air forces due to motion are dealt with under the general head of "Aerodynamics." A knowledge of air resistances is a primitive necessity in connecting the subject with the much older and well-established subject of "Dynamics."

In dealing with dynamics, the forces acting are frequently given by a simple fundamental law such as the theory of gravitation when accounting for the motion of planets and comets, and very many of the more complex reactions have been worked out. The corresponding fundamental theory of fluid motion has been known for more than half a century, but application to the determination of air resistances has proved to involve mathematical problems beyond the capacity of the times. Recourse has therefore been made to direct experiment, and in the early stages of aeronautical development almost every new idea could be tested. The number of variables under review has now grown so greatly as to exclude such a method on the ground of cost, and a period of fundamental experiment is being entered on. The object of such experiments is to find out what is happening to the air disturbed by the passage of a body in such a way that the results can be applied, with a reasonable degree of approximation, to a large number of related problems. Some success has been obtained in the case of aircrews, where the experimental data are so used that it is unnecessary to test every new design of aircrew. Extension to the airplane is gradually taking place.

For the same reason—expense—experiments on models have been used to cover the main field of inquiry, and the costly and frequently dangerous experiments on the full scale have, on the whole, been directed to crucial tests of the validity of the use of models. There has, of course, been a great amount of testing of aircraft in connexion with their value as fighting craft. At the present time, the value of such testing as an aid to design is very limited, detailed analysis being required to indicate lines of progress.

It then happens that the most comprehensive view of the subject of aeronautical principles is obtained from those aeronautical laboratories which deal with experiments on models, experiments carried out under almost ideal conditions in the artificial air current of a wind tunnel. The theory of the use of models becomes of great importance in aeronautics and has been studied extensively. When the maximum possible use has been made of the theory the position remains one for experiment, and full-scale cooperation is found to be essential for establishing a sound position. The theory of models has great value in showing the correct type of experiment and the method of comparison with the full scale. Finally, it has now been known that when certain precautions are observed in model tests the applications to full scale have an accuracy sufficient to give them a high value as an element in progress.2

1 Report, Advisory Committee for Aeronautics, 1909-10, p. 38.

FIG. 16.—Wind Tunnel.

Laboratory Experiments.—(a) The Wind Tunnel.—The number of class wind tunnels in existence in the world in July 1921 was probably between twenty and thirty. Of these, seven were at the National Physical Laboratory at Teddington, three
at the Royal Aircraft Establishment, Farnborough, and a number distributed amongst the private aeronautical firms of Britain. America has a number of channels of generally similar type, but with a unique example in one instance where the speed of the air current is very high. The oldest of the wind tunnels of importance in the development of aviation is that of Eiffel, and from it in 1900-10 came a number of experiments on wing forms at a time when flying-machines were becoming realities.

The Eiffel type of wind tunnel has been used elsewhere and in France a new installation has been erected at St. Cyr. The model of the wind tunnel is not now at La Göttingen University (Germany) and Koutchino (Russia). Owing to the general upheaval in Russia the last-named laboratory is closed, but it earned distinction in the years of its activity particularly in dealing with interesting experiments on fundamental points in the theory and practice of the day.

In general conception all wind tunnels agree in attempting to obtain a uniformly distributed, non-fluctuating air stream; and the tendency has been to increase the dimensions and the velocity attained in passing from one installation to a succeeding type. Economy of power for a given extension of experimental range is of great importance today, but it is readily obtained with large dimensions than with high speed. The best criterion, things other being unchanged, is the product of diameter and velocity, and judged on this standard the largest installations of the various countries do not differ materially.

At the Royal Aircraft Establishment (formerly called the Royal Aircraft Factory), Farnborough, a speed of 100 m.p.h. (nearly 150 ft. per sec.) is reached in an air-stream 7 ft. square. At the National Physical Laboratory a speed of 110 ft. can be produced in a stream 7 ft. deep by 14 ft. in width and forces on a model in this tunnel are more nearly simulated to those on a full scale model than in any other of the type so far seen at the present time. The great desiderata are uniformity of distribution of velocity across the stream and freedom from large pulsations. Uniformity of distribution is almost automatically secured by using a straight air stream. Once curvature has been introduced by the turning of corners the difficulties of producing uniformity are formidable. On the other hand the delivery of large volumes of air—nearly half an million cub. ft. per minute in the large tunnels—requires special consideration if large eddies in the room with consequent pulsations in the flow are to be avoided. There is an opinion, supported only by crude experiments, that the N.P.L. type of channel is somewhat less fluctuating than the Eiffel type. For the delicate adjustments required in the measurement of stability coefficients high value attaches to the steadiness of the air stream.

In dealing with efficient wing forms, where the lift may be more than 20 times the resistance, it is important that the direction of the air be accurately known and remain fixed; one-tenth of a degree is considered to be the maximum permissible error. It is found by experience that in a parallel walled channel the wind sets itself parallel to the walls with the accuracy desired. Freedom from large variations of velocity across the section depends not only on the straightness of the chutes but also on the distance over which the air has been in contact with solid walls. From some experiments by Stanton it appears that the final distribution of velocity in tubes is not reached within 20 ft. of the entrance. The Eiffel type and the score of space required and power needed such proportions are unrealizable in wind channels and in other respects would be disadvantageous. Some variation of velocity distribution from point to point along a wind channel is then to be expected, there being a retardation of flow at the walls and an acceleration in the centre. A relative error of 10 per cent of the mean speed is allowed along the working section of the channel. For experiments on warships, struts, etc., these departures from uniformity are unimportant but in the case of long models of airship forms there is introduced a further objection, since the surface of the model in the wind tunnel model. It has been suggested, and experiments are being carried out to give effect to it, that the objectionable effects of the wind channel might be minimized by the substitution of a slightly diverging wind tunnel. The methods used for the work of sections are the parallel part. It appears to be possible by such device to increase substantially the ease and accuracy of tests on airship forms.

The flow of air in a wind tunnel is eddyng and on this account a difference from motion through still air exists. So far, however, no suspicions have been aroused as to the inapplicability of model tests on this ground. Some eddies produced in the working of the wind tunnel would be the same in the full scale model as on the floor of the building housing a wind tunnel, below the intake, it will be noticed that isolated miniature whirlwinds are produced. Some of these are vigorous and the base will clear a track amongst the sawdust whilst the core extends upwards to the tunnel mouth. The spin in such eddies is great and the effect of the forces experienced by a body in the air flow is considerable. Being spasmoid, the effect is easily avoided. The eddying of the wind will introduce modern knowledge may be of interest (see fig. 16).

The wind tunnel is housed in an unobstructed chamber a little longer than itself, a space of one and a half diameters between the walls is well being sought for the satisfactory admission of the air from the chamber to the tunnel. The cross section of the room should be 25 to 30 times that of the channel, otherwise the return flow of air from delivery to intake will produce fluctuations of undesirably large magnitude. The tunnel, which is placed properly is straight and is generally in any eddies in the building, this being effective in securing symmetry of air flow in the working section. Taking the diameter of the section—whether square or circular—as a standard, the tunnel would have an overall length of 10 to 15 diameters made up of a parallel section and intake four or five diameters long, having a rounded entrance and honeycomb, a cone connecting this working section to a circular tunnel, is enclosing the aircrew, which of the mean flow and an observer at an aerodynamic balance is conscious of a sharp blow on his apparatus. To eliminate these whirlwinds sufficiently a honeycomb is placed across the intake, the cells being small compared with the dimension occupied by the wind. The power of the wind energy of the power plant may be dissipated by the frictional resistance of the honeycomb and some appreciable length of tunnel is required to permit of the levelling-up of the flow before reaching the working section.

The design of a wind tunnel will be seen to involve much study if more than a very moderate degree of refinement of experiment be required. The design of the wind tunnel introducing modern knowledge may be of interest (see fig. 16).

The aircrew giving steady flow is one of small pitch-diameter ratio but otherwise similar in characteristics to those used in aerial tunnels. The pitch-diameter ratio gives the wind higher values giving rather greater economy of power and less steadiness. With careful design of aircrew and cone the divergence into the walls will be made large with resulting economy of power and no loss of steadiness.

The most modern method of dealing with the delivery stream is to divide the building into two parts by an openwork brick wall. In the return flow the air is broken up to dimensions which do not greatly affect the steadiness of the air when it again enters the intake. In one instance, in addition to the partition wall, there is a structure closely surrounding the delivery from the aircrew; this delivery is in the form of a jet which impinges on the end wall of the building, and splashing over it, reaches the corners and forms rollers along the four walls. The structure over the jet is designed to break up the aircrew more perfectly than the aircrew and the partition wall. Instead of the free jet spreading at the wall it is distributed through tubes in the covering structure, the spacing being such that equal volumes of air are delivered through each unit of area of the distributor. The aircrew is opened progressively as the wind tunnel increases and increases to cover the whole area just before the aircrew section. It is possible to reduce the velocity at which the air returns to the room to 5% of that in the jet without the introduction of appreciable back pressure at the aircrew.

Methods of Measurement of Velocity of Air.—Having secured uniformity of distribution and a degree of steadiness sufficient for the type of experiment to be performed, it is necessary to measure the velocity. So far there is known of obtaining a standard of reference using a wind channel; the only one measure—possibly two—of absolute air speed appears to have been made under precision conditions. The particular measurements made on a whirling arm and in the William Froude National Tank at the National Physical Laboratory

AERODYNAMICS

The study of the motion of water or any other fluid will give the essential information. A striking experimental investigation of the reality of the law of equivalence in certain cases was made at the National Physical Laboratory. The motion of air past a square plate was observed and photographed. Smoke admitted to the current showed fluid impinging on the plate and spreading in the water. At a very low speed it was easy to detect a windings of the air round two axes roughly in the direction of the stream. A section of the stream across these axes would have shown particles moving in spirals winding inwards. This was the reproduction of a very notable change occurred in the type of motion. Instead of the spirals retaining a steady position, the smoke showed instability had occurred, and periodically loops formed across the two axes, broke away and travelled down stream. It is known by the principles of dynamical similarity that it is possible to produce similar flow in water. Exact conditions for the second experiment follow from those of the first. Further photographs show that the comparison of types of flow is exact within the limits of observation. Neither of the motions described is the usual form of whirl. The next question is, what type will be. It says, quite definitely, that if a given type of motion, eddying or otherwise, exists under certain circumstances, there are sometimes a great number of other circumstances in which the same type of motion must occur, and it lays down in precise terms the other circumstances in their relation to the given type. The instance given above related to change of fluid; other changes might be those of velocity or size. Clearly the change of size covers the relation between model and full scale.

Dynamical Similarity.—The understanding of the laws of aeronautics in aeronautics and gunnery has been greatly assisted by the theory of dynamical similarity. An early formula was given by Lord Rayleigh and had a marked influence on progress, not only in Britain but abroad. In the later publications of the Advisory Committee for Aeronautics numerous references are made to aeronautical applications of the principle.

All the world is familiar with the idea of similarity in some form or other and there is little difficulty in appreciating the statement that human beings are similar to each other or, more accurately, are nearly similar; the horse would not be included so readily in the category of animals similar to man. The idea of dynamical similarity with its meaning that what is more usually applied only to concrete bodies. Motions may be exactly similar, nearly similar, or very different, and in the case of an invisible fluid like air the eye is no guide to comparison. It is true that air may be coloured by smoke and the motion followed and that some work has been carried out on such basis. When it is found, however, that the fluid may be changed without loss of essential characteristics of the motion, a new line of attack is opened and

\[ \frac{p}{\rho} = \frac{v^2}{L_5} \]  

where \( M \) is the symbol for mass, \( L \) for length and \( T \) for time. Velocity, \( r \), is represented by \( L_1 \), density by \( L_2 \) and viscosity by \( L_3 \) (See footnote 1). Expressed in the form of an equation the assumptions so far made amount to

\[ R = \frac{f(p, l, r, v)}{T^2} \]

where \( R \) is the resistance, \( f \) a typical linear dimension of the body and \( f/a \) a functional form which depends on the shape of the body. It is common to include in \( f \) the presentation of the body to the wind as given its shape, but this is usually excluded at will by introducing angular coordinates into the arguments of the function. The principle of dynamical similarity states that \( f \) may only have such a form as will make the dimensions of the two sides of (2) agree. For down it must, if true, satisfy the condition that the numerical values of the two sides of the equation are equal and that, independently, the dimensions are equal. The latter point may be sufficient to give useful mathematical form to the physical ideas. For example, imagine an airplane to be flying down through still air at some known speed. The resistance or drag will depend on its shape and size, its speed, the density of the air and the viscosity of the air. For the moment it will be assumed that the drag is dependent only on the quantities enumerated.

\[ R = \frac{p_0 F}{\rho L_5} \]

Footnote 1: Advisory Committee for Aeronautics, and Applied Aerodynamics, L. Bairstow.

Footnote 2: The coefficient of viscosity used in dynamics is denoted by \( \nu \) and referred to as the "kinematic coefficient of viscosity." The other common coefficient \( \mu \) is related to \( \nu \) by the equation \( \nu = \mu \rho \).
No dynamical equation depending on the quantities mentioned earlier can exist which is not included in (3). For the purpose of comparison of resistances it has been found convenient by the aerodynamical laboratories to tabulate the value of \( F \frac{l}{\nu} \) for various bodies and to use the symbol \( k_b \) for it. Equation (3) may then be written alternatively as

\[
F \frac{l}{\nu} = k_b \left( \frac{\rho u^2}{2} \right)
\]

and in this form several points of importance are evident. To make the case specific, consider the resistance of a sphere in air as obtained from a wind-tunnel measurement. If the dimension \( l \) is identified with the diameter \( d \) of the sphere it will be noted that \( \frac{\rho u^2}{2} \) is an experimentally determinate quantity and from it values of \( k_b \) are determined. An examination of the dimensions of \( k_b \) will indicate that they are zero; the coefficient is therefore a pure number and so of international validity. Another method of statement would be to say that the numerical value of \( k_b \) is independent of the system of units used so long as the system is self-consistent. Measurements of force may be made in dynes, mass in grammes, lengths in centimetres and time in seconds to meet the standards of the physicist. Alternatively the engineer may use the force unit of lb weight, the slug as a unit of mass, the foot for length and the sec. for time, or, if preferred, the tons of pound, the mass unit of pound, and the foot and second. In all cases the tabulated values of \( k_b \) would be identical. There are further advantages of the system; \( k_b \) is independent of the aerodynamical law and is almost independent of size and speed, so that comparison between model and full scale is readily made by comparison of the corresponding values of \( k_b \). The extent to which the two agrees is a measure of the utility of experiments on models.

Equation (4) also shows that \( k_b \) depends on a single variable \( \frac{v^2 l}{\nu} \) not separately on \( v \), \( l \), or \( \nu \). On theoretical grounds alone therefore we may say—for our special assumptions—that \( k_b \) will not change if the velocity of the same body be doubled in a fluid having twice the viscosity. The kinematic viscosity of air is 12 or 13 times that of water at ordinary temperatures and hence the resistance coefficient will be multiplied by a factor of about 12 or 13 times to the power of two. Stanton has shown that this is true for smooth and rough pipes by testing with the two fluids in the same apparatus. The law was used in the calibration of the pitot-static pressure tube.

\( \frac{v^2 l}{\nu} \) may be kept constant in many other ways; if air be the fluid used in two experiments, then \( v \) and \( l \) may vary so long as the product is constant. A model aeroplane to one-tenth scale would give a resistance coefficient on test equal to that on the aeroplane at one-tenth the speed. Since the speeds of flight reach 200 ft. per sec., this law is not applicable to the complete aeroplane, for compressibility of the air would be very important in the model test at 2,000 ft. per sec. In certain cases it may be necessary to use struts, and then it is easily possible to make models larger than the reality and so to extend the equivalent speed from that of the wind tunnel to that of flight.

It should be noted, however, that there is no reason to satisfy the law of corresponding speeds, i.e., \( \frac{v^2 l}{\nu} = \text{constant} \), and hence there is no reason to satisfy the law of corresponding speeds, i.e., \( \frac{v^2 l}{\nu} = \text{constant} \). That is to say, the hypothesis that an exact law existed is worth examination.

Since \( R \) varies as \( \frac{v^2 l}{\nu} \) it follows from (4) that \( k_b \) must then be a constant for all values of \( \frac{v^2 l}{\nu} \). In such a case the law of corresponding speeds is of no importance, for \( k_b \) can be deduced from a test at any speed on any size of body. It needs little effort to see that if \( \frac{v^2 l}{\nu} \) varies a little from proportionality to \( \frac{v^2 l}{\nu} \) the motions of model and full scale will be nearly similar and that the function \( \frac{v^2 l}{\nu} \) is relatively unimportant. It is on this variation from strict theory that aerodynamics depends in many applications of model results. Since there is no absolute theoretical sanction except in the case of corresponding speeds, the identity of the values of \( k_b \) on the model and full scale must be tried out in a sufficiently large number of typical cases if reliability is to be established. This has to be done. On the whole the equation which led to the conclusion that the pressure divided by air density and square of speed is a function only of \( \frac{v^2 l}{\nu} \). Special photographic anemometers were made by the Royal Aircraft Establishment for use in flight and the pressures over a section of the upper and lower wings of a biplane were measured.

The range of variation of pressure on the full scale is faithfully reproduced by the model and in three of the four comparisons the actual numerical agreement is complete within the accuracy of measurement. The fourth comparison is a little more unfavourable and may be explained and some doubt exists as to its reality. Repetition of the experiments has not yet been made. Generally, however, it is clear that in heavier-than-air craft the use of models is amply justified. The range of full-scale experiment precludes any statement of value.

In the course of the investigations of the variations of \( k_b \) with speed and shape it was found that there occurred an appreciable magnitude at the low speed of wind tunnels but that the values tended to a limit. It is the value of \( k_b \) at the limit of capacity of wind tunnels which is taken in default of correcting factors determined from a comparison between full-scale and model experiments. On the score of cost it is not practicable to increase the size of wind channel or the speed of the wind indefinitely and the highest value of \( v^2 l \) appears to be obtained most economically by large size rather than by high speed. There are some other advantages of the system: the completeness of detail possible increases with the size of model and one of the claims in favour of the large \( 7 \text{ ft.} \times 14 \text{ ft.} \) channel at the National Physical Laboratory is that the model will be so large that an air screw can be fitted to it and the combination of airscrew and aeroplane tested under conditions very closely resembling those in flight. The Effect of Compressibility on the Motion of Air—The law of corresponding speeds expressed by the relation \( \frac{v^2 l}{\nu} = \text{constant} \) is peculiar to the assumptions made in obtaining (4) as to the experimental factors which have appreciable effects on resistance. There is no reason why the laws of the effect of viscosity on resistances, each law being applicable under limited conditions. The method of finding the appropriate law is clear; the process begins with a statement of the physical quantities and measurements involved and concludes with the statement of the value of the correct dimensions has been found. The conditions may be so complex that the answer, when obtained, is of little value; in general the theory of dynamical similarity is useful only when the number of important variables is less than five. The similarity here is in the process of linking the problem to a fluid characterized by density and viscosity only, an extra property defining its compressibility is included. There are various ways of expressing compressibility and the most obvious way would be through an elasticity modulus. Density is included already in the properties considered, and the velocity of sound in a fluid is determined by the ratio of the modulus of elasticity to the density. It has therefore come to be usual to assume that the velocity of sound is a convenient variable when investigating the effects of compressibility of a fluid on the resistance to the motion of a body through it.

The equivalent to equation (2) for the extended problem is

\[
\frac{v^2 l}{\nu} = \text{constant}
\]

and restricting the form of \( f \) to that which satisfies the theory of the dimensions

\[
\frac{v^2 l}{\nu} = k_b F \left( \frac{v^2 l}{\nu} \right)
\]

To satisfy the theoretical conditions which guarantee the constancy of \( k_b \) it is necessary to satisfy simultaneously the equations

\[
\frac{v^2 l}{\nu} = \text{constant}, \quad a = \text{constant}
\]

for such variations of size, speed and fluid as are at disposal. Once the fluid is specified, \( v \) and \( a \) are given and no law of corresponding speeds exists. Various proposals have been made to use a gas such as carbonic acid in one experiment and air in another, but little use appears to have been made of (6) in the form given. The formula for the pressure due to a pitot to find the force acting on a body—(1)—is a particular case of (6). That the form of (1) agrees with (6) can be seen by an expansion of the functional operator of the latter in powers of \( \frac{v^2 l}{\nu} \) using Maclaurin's theorem. Such an expansion will be useful so long as the effect of compressibility is small and the argument \( \frac{v^2 l}{\nu} \) small. There is a further simplification in the case of the pitot tube since the resistance does not depend measurably on \( \frac{v^2 l}{\nu} \). From experiments on the issue of steam from the nozzles of aero-planes and the measurements of pressure on a shell in flight it appears that in many cases

\[
R = \frac{3}{16} \frac{F}{\rho \frac{v^2 l}{\nu}}
\]

is a type of formula applicable to the maximum possible pressure on a moving body for speeds ranging from a few in. per sec. to 2,000 ft. per sec. and upwards.

1. Advisory Committee for Aeronautics, 1911-2, p. 41.
It is possible that a correcting factor will be introduced into the design of airscrews to allow for compressibility of the air. In such a case, resistance coefficients based on (7) would provide the first approximation to a rational formula.

Tests of the Water Resistance of Flying-Boat Hulls.—Applications of dynamical similarity extend over the whole range of physics and an exhaustive discussion would lead far away from aeronautics. One other illustration is required to show the origin of the law of corresponding speeds applied in naval architecture to surface-moving craft. Experimentally it has been found that the resistance of surface craft at high speeds depends greatly on the generation of waves. If attention be concentrated on this new aspect of resistance it will be found—by methods already indicated—to give the law of corresponding speeds associated with the name of Froude.

At any point of a curved surface the pressure is proportional to the head of water above that point and will be increased if a wave crest exists in the neighbourhood. The pressure depends on the head and on the weight of unit volume of the water; alternatively the weight may be expressed as the product of the density of the water and the acceleration due to gravity. Now consider the problem of similar motions between a ship and a model of it. The scale of the model must apply to the scale of the waves if similarity is to exist. It can be said therefore that the resistance depends on a linear dimension $l$, velocity of test $v$, density of water $\rho$ and the acceleration due to gravity $g$. The appropriate formula then follows and proves to be

$$R = \rho g l F (\frac{v}{g})^n$$

(8).

The law of corresponding speeds is therefore $\frac{v^2}{g} = \text{constant}$. When dealing with comparisons of motion on the earth's surface, $g$ is constant and the law states that the speed of test for the model varies as the square root of the scale. This condition ensures that the waves in model and full-scale trials shall be similar. Equation (8) may apply in other cases, such as the disturbed motion of model and actual aeroplanes in free flight, the governing factor being the dependence of the motion on gravitational attraction.

**Summary of the Aeronautical Uses of Dynamical Similarity.**—In measurements of resistance to the motion of a body through viscous fluid the correct law of corresponding speeds is that $\frac{v^2}{g} = \text{constant}$: this is applicable so long as the velocity of motion is not more than about one-quarter of that of sound. At higher velocities compressibility of the fluid modifies the flow, the changes depending on a further factor $\frac{a}{v}$, i.e., on the ratio of the velocity of the body through the fluid to that of sound in the fluid.

If the wave-making resistance alone be considered the law of corresponding speeds for terrestrial surface craft is $\frac{v^2}{l} = \text{constant}$; where resistance depends partly on wave-making and partly on viscosity it is generally assumed that the two can be treated by special assumptions. A very accurate method of treatment of the complex problem does not lead to practicable formulae.

**The Resistances of Bodies of Various Shapes.**—A somewhat sharp division exists between the resistances of wings and aerfoils and those other bodies with which aeronautics is concerned. In the latter cases the resulting air force is either directly opposed to the motion or is little inclined to it. In the case of wings at the most efficient angle of presentation the resultant force is almost normal to the direction of motion. Since there is always a real drag the direction of the resultant force must fall behind the normal but the amount may be less than three degrees.

It has been found experimentally that all aeroplane wings—whatever their variations of shape—have certain common characteristics. The best ratio of lift to drag is obtained only at a particular angle of attack of the wing to the air and a considerable loss of efficiency is incurred if, as is usual in aeroplanes, departure from this angle to the extent of $5^\circ$ or $6^\circ$ be permitted. At the highest speed of flight of the aeroplane of 1921 it is improbable that the lift exceeds 12 times the drag, whilst the maximum ratio exceeds twenty.

Apart from efficiency there is a limit to the greatest force which can be obtained at a given speed by a wing of finite area. Omitting very special complex wings for the moment, the limiting force at any given speed is obtained when the wing is inclined at $15^\circ$ or $20^\circ$ to the wind. One of the most efficient types of wing form for high-speed flight has a limiting lift of about 7 lb. per sq. ft. at a speed of 50 m. per hour. Other forms of fixed section are known which give 12 lb. per sq. ft., but the same angle of incidence. Experiments with aerfoils have been that, so long as the shape of the section is invariable, high loading at the angle of maximum lift cannot be obtained at the same time as high efficiency for maximum speed.

Much attention has been paid therefore to flexible and variable wings; if it were possible to vary the area of a wing at will without introducing unreliable mechanism or adding greatly to the weight of the wing structure that solution would offer the maximum aero-dynamic advantages. It should be pointed out here, that the addition of weight to an aeroplane in such a place as not to add directly to the resistance leads to an immediate and calculable indirect increase of resistance at a given angle of incidence and the amount may be estimated as about one-eighth of the weight under favourable conditions. So far no satisfactory proposals exist for the mechanical variation of the area of the wings of an aeroplane. More practical success has met the endeavours to vary the section of a wing of given size so as to obtain the advantages of high lift and consequent low speed for alighting and high efficiency at flying speeds. It has already been shown that either condition may be obtained by a wing of fixed section. A further general observation is that the high-speed wing is thin and flat whilst the high-lift wing is thick and greatly curved. Means of constructing flexible rils for wings to admit of continuous change from one shape to another have been developed and the mechanical difficulties do not appear to be insuperable.

A less obvious method of attack has shown greater promise. Mr. Handley Page1 found by experiments in a wind tunnel that the properties of high lift could be obtained by allowing air to pass through the front part of a wing from the lower to the upper side. By dividing the wing of an aeroplane into a small aeroplane hinged at its leading edge and a device which the device becomes both mechanically and aerodynamically effective.

The motion of an aeroplane is now realized to be dominated by other considerations than those of lift and drag and it may be that a particular high-lift wing would be useless because it led to failure of lateral control at low speeds. This point is of growing importance and aeroplane design can no longer ignore the complex interactions of aerodynamic properties. For this reason it may be anticipated that the full advantages from variable wings will not be obtained immediately but that the processes of evolution will be followed. Past history has been simpler; early experiments by Langley (1896) covered the properties of flat plates used as aerfoils and laid the general foundation of practical aviation. Lilienthal later showed that curved surfaces were more efficient than flat ones and attention was given to sections suggested by bird wings, a subject of interest still occupying the minds of designers. With little guidance forms, the early pioneers of flight, Wilbur and Orville Wright, Farman, Bleriot and others, introduced wing sections in the period 1905-10 and on these Eiffel based his first series of experiments.2 Design then began to be regularized. One of the more promising wing sections examined by Eiffel in his wind tunnel at the Champs de Mars, designated "Bleriot 11 bis," was adopted by the Royal Aircraft Factory for the BE2a. In 1911, the National Physical Laboratory adopted this form as the starting-point for systematic variation of wing form. In the series of experiments which followed, the thickness of the wing was changed, also its shape on upper and lower surfaces and the bluntness of the nose, and in each case measurements of lift and drag were made. From this series it was possible to make a rational choice of wing section to fit the conditions of the day. The absolute maximum of aerodynamic efficiency demanded a wing too

---

thin for structural reasons and the Royal Aircraft in the early days of 1913 designed the RAF6 wing on the basis of these experiments for the development of the aeroplane BE2. At a later stage, as engines of greater power were produced, further experiments led to improvements in the design of the RAF6 wing, which was finally adopted by RAF15 (May 1915). It was found that the advantages of the latter at high speeds were appreciable in spite of the increase of wing area necessary to maintain a reasonably low landing speed. Many new types of the wing were made and various new wing forms and those showing value on preliminary test have been investigated. It has invariably been found that guesses have been inferior to the results of systematic methods, though it is sometimes possible to facilitate the latter by the use of an aerodynamic form. The air speeds have been divided into wind, field, and road. The air speeds have been determined and the wind, field, and road areas have been divided into wind, field, and road speeds. The results have been shown in curves as well as tables and, if uniformity in scale be adopted for the curves, comparison of wings will be facilitated, and the superposition of the curves will be facilitated also. The error should be greater if the work of the various designers produces nearly the same result. This is particularly true in matters relating to the reliability and safety of aircraft.

The idea of stability as applied to motion is very old and standard methods of dealing with mechanical problems were gradually developed by the mathematicians of the last century. Laplace applied his knowledge to an examination of the stability of the solar system, i.e., he accepted the theory of gravitation as accounting for observations and made an extension to see whether the motion was permanent or in a state of change. The ideas of stability are quite different from those of aerodynamics and at the present day it is safe to say that the work of the aeroplane designer is largely in this domain. It is true that some rough generalizations exist and are acted upon; by placing the centre of gravity of an aeroplane very far forward longitudinal stability is ensured whilst a rearward position tends to instability and danger. Similarly, the fin's dihedral angle on the wing is known to affect lateral stability. Present-day (1931) aeroplanes border on neutral stability for the conditions of straight forward flight and this has come about by trial and error, corrected by the like of wisdom and judgement. Stability means that the aeroplane is maintained in the air in the condition in which it leaves the works. The worst attempt to make very large aeroplanes, 20,000 to 50,000 lb. in weight, have led to early disaster owing to the inability to approach, on such scale, the necessary degree of refinement of control and stability. Alternatively it may be said that the attempt to develop large aeroplane has sometimes been brought to a state where the work of the future becomes too much of an imponderable to be of value.

Broadly speaking the quality called stability is readily defined. An aeroplane is taken into the air and a given state of motion produced by the pilot and maintained for some time. The operation does not involve stability but requires adequate control. When flying steadily suppose that the pilot ceases...
to operate but keeps his muscles rigid and without disturbing the motion deliberately produces a condition in which the aeroplane has to control itself in gusts of small size. If the motion be stable, no great changes will occur as a result of the pilot's relinquishing of control. A small amount of pitching, rolling, yawing and side-slip, etc., will occur but on the whole the speed of flight and the angle of incidence will remain at the same value as at the beginning; the wings will not change their angle of bank greatly nor the turning increase or decrease. It is evident that this distinction to stability there are many instabilities possible, will magnify the effects of a gust with greater or less rapidity and the motion will depart from the initial state to some other stable state. It rarely happens that this second state is a comfortable one. An aeroplane which is unstable in normal flight will usually be stable upside down and may be so stable in that position as to be uncontrollable. The time taken to pass from one state to another is often only a matter of a few seconds, rarely as long as a few minutes.

In the very early days of flying the problem of getting into the air at all took first place in importance. The aviators of 1903 and 1904, watching the weather and one of them had a standard test for satisfactory conditions. Standing with his feet apart, he dropped a feather from the level of his shoulders and if it fell outside his feet the wind was too great for flying. The record of these early days and the shortness of life of the aviators are sufficient testimony to the consequences of the extreme forms of instability. The revolutionary step which made it possible to keep the air for an hour instead of a few minutes was made by the Wright brothers when they introduced wing warping as a lateral control; there is little reason to doubt that the statement that flying still remained an acrobatic feat. A study of the technical papers of the period 1908-14 will show how slowly the idea of banking an aeroplane entered into the development of aviation. It is noted in March 1912 as a possible cause of accident that the pilot "is reported to have endeavoured to rise when making a turn." Not until April 1913 do we find vertical banking by Chevillard followed by upside-down flying and looping by Pégoud in Sept. of that year.

A prominent place in the technical journals was devoted to accidents and a perusal of these shows that all types were liable to fail as late as 1913. A series of accidents to monoplanes occurred with their flight of August of 1912, whilst a committee was formed to investigate causes and to suggest lines of development. The findings of this committee have had a marked influence on British aviation and the paragraph relating to stability is here quoted:

"The Committee desire to urge the importance of the general investigation into the stability of aeroplanes, whether monoplanes or biplanes. The experimental data at present available are not sufficient to allow a complete theory to be formulated. It is understood, however, that the work of the Advisory Committee has now been carried to the stage at which the problem can be attacked with hope of success, provided that the necessary facilities—a large wind channel in a sufficiently big enclosed space—be put at their disposal, and the Committee recommend that the Advisory Committee be asked to continue the further investigation into the stability of the aeroplane as a matter of great urgency, and more especially to examine the question of inherent lateral stability, suggestions towards the solution of which have been given by the experiments of Lancaster and the calculations of Bryan."

The investigation here started led directly to the stability experiments on REs and BEs, a combination of full-scale flights at the Royal Aircraft Factory and model and theoretical preparatory work at the National Physical Laboratory. Before dealing with the results, a return to early times will be made to indicate the position of the theory of stability.

Up to the end of 1909 the chief writers on the stability of the aeroplane were Bryan,2 Ferber,3 Lancaster,4 and Soreau.5

The most complete method was that by Bryan. The papers all advanced the study of the subject in some measure but the appearance in 1911 of Bryan's book Stability in Aviation laid the foundations of the subject as now known to us. About the same time other workers were entering the field, amongst whom may be mentioned Knoller,6 Bothzat7 and Reilsner.8 From that time the theory of stability has been far ahead of practice. Developments have been made to cover circling flight, disturbed motion, the effects of gusts but all are extensions of the theory of dynamical stability as given by Routh and applied by Bryan to the aeroplane. There is little doubt that further extensions will be made as required, but the immediate need is the devotion of existing knowledge to practice to a far greater extent than has hitherto occurred. As in other branches of research the World War has had an adverse effect in curtailing opportunities for reasoned progress.

In March 1913 a report10 was issued showing the possible applications of the theory of stability from the National Physical Laboratory. The mathematical analysis cannot be useful unless a number of quantities, known as resistance derivatives, can be obtained from experiment. The report in question represents the first systematic attempt to apply experimental research to the problem of finding stability derivatives for application of the theory. A discussion is given of the meaning and origin, from the physical side, of the resistance derivatives and rough estimates were made as to the ranges of the quantities for the various types of aeroplane. As a result of these experiments data were obtained and a table of some 18 derivatives deduced covering the longitudinal and lateral stability of an aeroplane in normal flight. There were a number of suggestions which were in the understanding of the relation cause effect which were of importance in the infancy of the subject.

By such a preliminary examination on the model scale, the problem to be looked to, was clearly defined. The now well-known "phugoid" oscillation was then observed and only indicated by calculations. It is indeed possible that up to that date longitudinal stability did not exist apart from the very special design of Douglas biplane. The mathematical theory indicated quite clearly that special shapes were unnecessary and that aeroplanes of more usual form could be made stable by attention to the distribution of weights and the form of the aeroplane itself.

In particular, the importance of an dihedral angle on the wings and an adequate fin and rudder were shown in relation to lateral stability.

In the course of the 12 months which followed great progress was made, a series of papers from the National Physical Laboratory, the effect of varying essential quantities, such as the Centre of gravity of the aeroplane, the amount of area of the tail plane, the extent of the dihedral angle, rudder and fin area, etc., was examined in detail. It was seen that this representation of the aeroplane as a system since there is a relation between the dihedral angle on the wings and the appropriate fin and rudder area.

Further, the exact method of inherent adjustment of an aeroplane to the wind was shown and the details of flight of a longitudinally stable aeroplane in a natural wind obtained. This was done not only for uncontrolled but for controlled flight. By the summer of 1914 the application of the results of the theoretical calculations to mechanical devices for controlling it were being envisaged, but the outbreak of the war broke the continuity and the subject still remains at that point of theoretical development.

In the meantime full-scale experiments were being made at the Royal Aircraft Factory.12 A few extracts from these reports are of historical value and are here reproduced:

"Although completely controllable under all circumstances by means of the elevator, it has been found that the B.E.2a aeroplane, fitted with the old tail plane (TP) was not stable with the elevator-freg or even locked. . . .

Two methods of experimenting have been adopted. (1) Variations in the position of the central gravity of the or perpendicular to the position of the wings."

(2) Variation of the position of the centre of gravity of the aeroplane relative to the position of the wings."

"Experiment (1) with tail (TP). Area of tail 61 sq. ft. Centre of gravity of tail 10 ft. 32 ft. of the leading edge. At a height of about 2,000 ft. the elevator control lever was held in a fixed position. After a short time, a steady dive developed, which was allowed to continue as long as the conditions were such that there was no tendency for the path to revert to the horizontal. . . . It was found that there was just as much tendency for a steady aero to be developed as a dive . . . ."

10 Reports, Advisory Committee for Aeronautics, 1913-4, pp. 385-594.
"Experiment (2). Another tail was tried (TP2). A long glide was also made with the elevator locked. During these flights a marked improvement in the behaviour of the machine was obtained, damped phugoids being described. It may indeed be said, however, that the other tail proved the BE2 to be capable of flying indefinitely with the elevator locked in winds with gusts up to 30 m. per hour.

"Experiment (3). The same tail plane was fitted and the condition of the airplane with the elevator left free was examined. It seemed to the writer that considerable improvement took place in the centre of gravity was considerably further back. This very backward position of the centre of gravity, of course, made the aeroplane quite unstable, and increasing dives or rears were performed almost as soon as the machine was left free.

"Experiment (4). The centre of gravity was brought forward and a considerable improvement was obtained. It was now found that even when the interplane struts were lengthened and the whole of the elevator control lever and did not have to be reversed to the flashing form of the wing, that the control lever was completely and that the oscillations were not severe or of much period.

"Apart from the practical utility of these experiments in developing the particular tailplane in question their wider significance underlies the fact that they agree with and confirm the model experiments on the full scale both as regards the characteristics of the tail plane and the interference of the main planes with them. The two sets of experiments give data from which a tail can be designed for any aeroplane to give any degree of longitudinal stability required.

"It appears from recent investigations of accidents that the type of instability generally met with is not avian in nature but an effect of the instability is serious and epidemic failures to control have been traced to this cause alone. Some photographic records of longitudinal motion which were taken in 1914 will be found in the supplement to Aeronautics, published in the Wilbur Wright lecture for 1919. The actual time required for the testing of longitudinal stability is now so short that the production of records has been made an addition to the older established tests. The period has been steadily reduced, and the influence of the tests is not yet evident in new design.

"The case of lateral stability is the record of the early experiments at the Royal Aircraft Factory are of equal or greater importance than these investigations.

"RE: Rolling stability experiments, by Mr. Bush. The wing flap control were entirely abandoned and the aeroplane was flown at 75 m. with two turns without their use. The rudder was used for steering or was kept straight to avoid complicating the investigation.

"The evolution of the aeroplane bore out the theoretical expectations. Disturbance by a gust was followed by side-slip towards the low side, which brought the dihedral angle into effect, righting the machine. In both the above experiments the recovery from a roll seemed rather slow, and it was decided to double the amount by which the wings were set up.

"The results of the experiments were sufficiently satisfactory to warrant the abandonment of the warp and the use of wings and flaps for RE7 and other aeroplanes in course of design.

"RCA: RudderStick. With the rudder in a fixed position was next examined. Up to this point the aeroplane had been usually steered on a straight course, which made recovery quicker than was fixed, and disturbance was no longer possible. It was followed by a turn towards the low side as well as a side-slip. If the directional stability is too great, the increased speed of the outer wing will counteract the restoring effect of side-slip, and the aeroplane will continue to turn with increasing bank and angular velocity. The manoeuvre if not controlled ends in a spiral dive.

"Dec. 8 1913.—In this experiment, the rudder was adjusted for straight flight and turned to a side by the feet, friction of the heels against the floor making absence of rudder certain. When all was ready the aeroplane was disturbed by the wing flaps, which were then returned to their normal position. The experiment is rather delicate, as the position of the body will cause it to be turned, perhaps in one direction and unstable in the other. It appeared, however, that the aeroplane was just stable, righting herself slowly.

"Complete stability test. The aeroplane was flown from Long Valley and thence to Fleet, distances of 61 and 8 m., without the use of wing flaps or elevator. The wing flaps were left free as usual and the elevator was locked. The flying was very comfortable, and the pilot considered that the airplane would have been easier under these conditions would be considerably easier for a pilot alone.

"For normal flight the description of lateral stability given in these experiments still represents the position. The experiment is still delicate and it may be doubted whether any aeroplane has an appreciable degree of lateral stability. The early work on stability cleared the way to a large extent; the temptation to complex design for safety was removed and dangerous instability rarely exists so long as a pilot is alert. The introduction of aerobatics and the training of pilots to loop, spin, roll, etc., at the same times that it inspired confidence in the ability to control an aeroplane also led to conditions far removed from those of normal straight flight. It was then found that the stability of aircraft under extreme conditions has great importance, particularly when the angle of maximum lift has been reached or exceeded.

"A very large proportion of accidents arises from engine failure whilst near the ground. In holding up the nose of the aeroplane whilst attempting to turn back into an aerodrome, the pilot not infrequently stals the craft and violent lateral instability results. Recovery from the effects of this instability is rare and much study has been made of the phenomenon.

"There is now little doubt that it is too late to cure this instability but the methods of removing it are far less clear. The same cause which produces instability removes the effectiveness of the controls; it is probable that high-lift wings have characteristics antagonistic to those of stability and further investigation of the subject is required before satisfactory design for speeds less than that of stalling can be reached.

"More recent papers on various aspects of stability will be found in the reports of the societies and bodies dealing with aeronautics; there are no striking developments but much solid work has been done. Theoretical understanding is still uncertain, and there are difficulties in the nature of variation of nomenclature which make the comparison of work laborious and in an attempt to deal with this aspect of the problem of stability the Royal Aeronautical Society, acting as a sub-committee of the British Engineering Standards Association, has drawn up and recommended the use of a particular set of symbols and axes of reference.

"Still in its infancy as regards application, the subject merits greater attention. It is scarcely likely that the degree of stability—still undefined—thought suitable for military use will be that correct for civil uses. Extreme manoeuvrability is considered to be essential in first and second class machines. It is not until not wholly incompatible it is clear that a degree of stability can be introduced without discomfort in a straight and uneventful flying which is disliked for the purposes of aerial fighting.

"IV. MATERIALS AND METHODS OF MANUFACTURE

"The aircraft pioneers, being their own designers, builders and financiers, used the simplest design, manufacture and assembly, and the cheaper materials.

"Between 1912 and 1914 came a striving for efficiency; fixed charges were relatively high, and research costs were extremely great for the small output of the day; this continued to the quest for the best materials and made costly machining to reduce weight to be established. We must now set aside, for the moment, the aerodynamic advances made in this way were used, but as bulk production set in before schemes and tools for bulk production existed, aeroplanes had to be made regardless of cost until the tools were evolved.

"Standardization of materials, of sizes and of parts and components, notably bolts, nuts, brazing connexions, piping connections, etc., common to most types of aircraft, had previously to 1914 been started, but was extended in 1915 to cover tubes, brazings, methods of jointing, length of brackets, wheels and axles, ailerons, screws, etc. Also some of the larger components, wings, elevators, rudders and ailerons, which could be utilized on more than one type, were standardized. Master and workshop gauges were made and distributed to ensure interchangeability. Continuous records of tests led to the selection of the most suitable materials, and to standard specifications. These have been continuously evolved up to the present day, and their dissemination has spread far and wide much acquired knowledge.
The earliest steps in England, or indeed anywhere, to unify such standards were taken by the Royal Aircraft Factory at Farnborough in 1913. They were extended and improved as experience developed under the Aircraft Inspection Department (A.I.D.) in England (towards the end of 1915), and later under the British Engineering Standards Association, which in 1921 was instrumental in founding in Paris the “Comité International pour l’Unification Aéronautique” to internationalize the same work.

Components.—Fuselages, wings, undercarriages, tail planes and control surfaces, pontoons, and skids were not, in general, designed as self-contained units, i.e., their manufacture was usually completed during erection into the aeroplane. This involved hand-fitting, trial and error adjustment, constant inspection and slow production, while spares were not usually standardized or kept in stock. By 1915 each component became a unit in itself, made to limits, corresponding with the connection points, and interchangeability was safeguarded by the use of jigs and fixtures. By 1919 even components were subdivided into standardized parts, and the assembly of components into a complete aeroplane could be effected after delivery to the field. The jigs and fixtures were usually confined to the location of junction fittings on which the structure was completed. These replaced the fixtures of 1915, which held all members of the component in position during construction, but proved not to be satisfactory, owing to the distortion of the finished piece on removal from the fixture.

Girder types of construction, such as fuselages, wings, etc., were latterly constructed to jigs rather than on fixtures, in order that their truth of erection might be more permanent. Monocoque constructions, however, were always built on cradles or moulds, which definitely determined their final shape; the individual members, being free from initial load, were free from distortion on removal from the mould.

The development of portable gauges (gage points mounted on tensioned wires) occurred in 1916.

In 1917 component junctions were designed so that all positioning was done before installation, and were not, in general, installed in one direction being allowed on the remaining joints; the gauging of components was simplified thereby, and many of the more costly gauges could thus be superfluous or moved in conjunction with an interchangeability measure. Henceforward.

Woodwork.—Wood is eminently suitable for light weight and for obtaining a rapid output by machining. The mechanical properties and suitability of various timbers were known in 1911. Bamboo, the lightest timber, was found unsuitable in about 1911; it lacks uniformity in size, and is difficult to connect at the end of members. Ash (Fraxinus excelsior) and hickory (Carya alba, Hirtchis ovala) were early used, but hickory is scarce, and variable in its mechanical properties, and ash is heavy as well. Ash is restricted to uses where high flexibility and shock-resisting are essential. Silver spruce (Picea Stichensis, Carr.) was introduced in 1913 for spars, struts, masts and other members, being uniform, light and suitable for machining for weight reduction.

Between 1913 and 1915 accurate information of the strength and elasticity of this timber was acquired. Methods of converting the timber to its working form was developed in order to nullify defects peculiar to coniferous timbers, such as spiral grain, cross and diagonal grain, dote or rot, gun pockets, alternating hard and soft grains, low density, wide-ringed timber and brittle or lifeless timber (brush). The great demand in 1916 in England led to the importation of unseasoned timber, needing to be conditioned for use. The French and Americans had already experience of this. Kilns were erected in England (on the Sturtevent system of drying). Humidities, temperatures and time periods of drying were determined. Control of the moisture-content of timber was found to be essential.

The larger aeroplanes in 1916 and 1917, and the demand in excess of supply of long lengths of long lengths joined together, the joints being situated at points of low stress. A study of various joints in 1918 led to the adoption of the plain vertical scarf joint with an inclination of 1 in 9, reinforced by bolts through the scarf joints and bound with fabric (see fig. 18). Shorter timbers glued together as laminae then became permissible for all spars, and defects could thus either be cut out or reinforced. Joints in these laminations, after being admitted for a period, were accepted in 1919.

To supplement the supplies of silver spruce in 1917 the following timbers were tried in 1918, the peculiarities of each being allowed for: Quebec Spruce (Picea abies and Picea niger, Link.), White Sea White Deal (Picea excelsa, Link.), White Sea Red Sea Deal (Picea sitchensis, Link.), White Sea Virginia Spruce (Picea Virginiana Link.), North Carolina Spruce (which is the same as West Virginia Spruce, but grown in North Carolina), Louisiana Red Cypress (Picea glauca, Carr.), Port Orford Cedar (Chamaecyparis Lawsoniana, Murr.), New Zealand Kauri (Agathis [Dammara] australis), Canadian White Pine (Picea Strobus, Link.), Canadian Black Pine (Pinus Strobus, Dobb.), Louisiana Red Oak (Quercus Rubra, Lam.).

Cypress, which is very variable, liable to brittleiness and unsuitable for gluing, was barred in 1916. Oregon pine, which is liable to fracture under shock, and may split when cut into small dimensions, was not used, and the use of knots in the deals could be allowed in laminations if the knots be dead. A method of obtaining uniformity of the member. Laminated struts were used in 1919, with fabric binding to safeguard against the opening out during storage. Early in 1919 box sections, which have all the advantages of laminating, were used, and their use continues.

About 1915-6 the glues used in the above processes were classified in three grades: (1) the best for aircrew; (2) for less highly stressed joints; (3) for unimportant details. Glue shops were maintained at a constant 70° Fahrenheit. Micro-investigation of glued joints proved the value of carefully preparing the timber and glue; this was necessary to reduce the glueing, and no longer needed in the 70°-room for long periods before gluing. Roughing of the surfaces to be glued was adopted to secure keying.

In 1915-6 it was found that if an entire series of laminations were glued in one operation, the operation could not be tolerated, but could be chilled before the clamping occurred. Later, by using trained crews and special appliances for quick gluing and clamping, the en bloc method using the more rapid output became possible and satisfactory.

Where heated conditions were necessary, the "liquid" glue or jelly glues (containing an ingredient which delays the setting point of the glue, thus allowing of ordinary temperatures—55° F. for assembly with inflammable Canadian glues) were adopted.

Metal Fittings.—In 1915 fittings for the structures, attachment of bracings, etc., were made of mild steel, a metal selected, no doubt, because it could be worked cold. This was often used in double sections to avoid too great an exposure of the structure to welding operation.

Woodwork.—Wood is eminently suitable for light weight and for obtaining a rapid output by machining. The mechanical properties and suitability of various timbers were known in 1911. Bamboo, the lightest timber, was found unsuitable in about 1911; it lacks uniformity in size, and is difficult to connect at the end of members. Ash (Fraxinus excelsior) and hickory (Carya alba, Hirtchis ovala) were early used, but hickory is scarce, and variable in its mechanical properties, and ash is heavy as well. Ash is restricted to uses where high flexibility and shock-resisting are essential. Silver spruce (Picea Stichensis, Carr.) was introduced in 1913 for spars, struts, masts and other members, being uniform, light and suitable for machining for weight reduction.

Between 1913 and 1915 accurate information of the strength and elasticity of this timber was acquired. Methods of converting the timber to its working form was developed in order to nullify defects peculiar to coniferous timbers, such as spiral grain, cross and diagonal grain, dote or rot, gun pockets, alternating hard and soft grains, low density, wide-ringed timber and brittle or lifeless timber (brush). The great demand in 1916 in England led to the importation of unseasoned timber, needing to be conditioned for use. The French and Americans had already experience of this. Kilns were erected in England (on the Sturtevent system of drying). Humidities, temperatures and time periods of drying were determined. Control of the moisture-content of timber was found to be essential.

The larger aeroplanes in 1916 and 1917, and the demand in excess of supply of long lengths of long lengths joined together, the joints being situated at points of low stress. A study of various joints in 1918 led to the adoption of the plain vertical scarf joint with an inclination of 1 in 9, reinforced by bolts through the scarf joints and bound with fabric (see fig. 18). Shorter timbers glued together as laminae then became permissible for all spars, and defects could thus either be cut out or reinforced. Joints in these laminations, after being admitted for a period, were accepted in 1919.

To supplement the supplies of silver spruce in 1917 the following timbers were tried in 1918, the peculiarities of each being allowed for: Quebec Spruce (Picea abies and Picea niger, Link.), White Sea White Deal (Picea excelsa, Link.), White Sea Red Sea Deal (Picea sitchensis, Link.), White Sea Virginia Spruce (Picea Virginiana Link.), North Carolina Spruce (which is the same as West Virginia Spruce, but grown in North Carolina), Louisiana Red Cypress (Picea glauca, Carr.), Port Orford Cedar (Chamaecyparis Lawsoniana, Murr.), New Zealand Kauri (Agathis [Dammara] australis), Canadian White Pine (Picea Strobus, Link.), Canadian Black Pine (Pinus Strobus, Dobb.), Louisiana Red Oak (Quercus Rubra, Lam.).

Cypress, which is very variable, liable to brittleiness and unsuitable for gluing, was barred in 1916. Oregon pine, which is liable to fracture under shock, and may split when cut into small dimensions, was not used, and the use of knots in the deals could be allowed in laminations if the knots be dead. A method of obtaining uniformity of the member. Laminated struts were used in 1919, with fabric binding to safeguard against the opening out during storage. Early in 1919 box sections, which have all the advantages of laminating, were used, and their use continues.

About 1915-6 the glues used in the above processes were classified in three grades: (1) the best for aircrew; (2) for less highly stressed joints; (3) for unimportant details. Glue shops were maintained at a constant 70° Fahrenheit. Micro-investigation of glued joints proved the value of carefully preparing the timber and glue; this was necessary to reduce the glueing, and no longer needed in the 70°-room for long periods before gluing. Roughing of the surfaces to be glued was adopted to secure keying.

In 1915-6 it was found that if an entire series of laminations were glued in one operation, the operation could not be tolerated, but could be chilled before the clamping occurred. Later, by using trained crews and special appliances for quick gluing and clamping, the en bloc method using the more rapid output became possible and satisfactory.

Where heated conditions were necessary, the "liquid" glue or jelly glues (containing an ingredient which delays the setting point of the glue, thus allowing of ordinary temperatures—55° F. for assembly with inflammable Canadian glues) were adopted.

Metal Fittings.—In 1915 fittings for the structures, attachment of bracings, etc., were made of mild steel, a metal selected, no doubt, because it could be worked cold. This was often used in double sections to avoid too great an exposure of the structure to welding operation.

FIG. 18.
was In of tacked to triphenyl-phosphate drawn Engine later, it tried and single is was was was bracing without exposure. The hose was bracing to prevent exposure. In 1919, the structure was built on the strut-tie principle without wire, giving quick erection and maintained its very well the truth of structure.

Dope.—The fabric stretched over the wings became slack after exposure to alternations of humidity. Prior to 1909, rubber fabric was tried, and alternatively, the plain cotton was tautened by painting with flour paste. In 1909, thin sheets of cellulose acetate were applied over the cotton, and later, the substance was dissolved in acetone and applied with a brush, camphor being used to keep the coat pliable; however, the camphor evaporated, and thereafter the dope cracked on exposure. The search for a suitable softener that did not evaporate from the dope was prosecuted. Tetrachlorethane was tried with success, but it proved dangerous to the operators applying it in enclosed places. Moreover, sunlight decomposed tetrachlorethane; to yield hydrochloric acid, which eventually attacked the fabric.

In 1919, benzyl-alcohol was tried with success. When the evil effect of light on linen and dope was discovered in England, a pigment varnish was introduced by the Royal Aircraft Factory (P.C.10) which protected the fabric and dope from light and increased the life of both. In 1916, a nitrocellulose dope was introduced, to economize in the acetone radicals which were in demand elsewhere for explosives. From 1916 onwards, the acetate and nitro dopes were used to them benzyl alcohol was added to render the film plastic, and triphenyl-phosphate to render the film waterproof and fireproof. After removing all saponifiable grease from the fabric, the dope was applied by hand in three to five coats, till 1918, when spraying was introduced for the coats other than the first, which needed to be well brushed in. Constant temperature and low humidity are required in dope rooms to avoid the deposit of water due to evaporation of the solvents.

Rubber Hose.—Rubber tube introduced in pipe lines to give flexibility is deteriorated by petrol and oil. In 1916, some resistance to petrol was introduced by using pure para heavily loaded with mineral matter and rather over-vulcanized. This withstand boiling petrol for one hour, and immersion for 23 hours, but its life in use is very short and it frequently required renewal after four months.

Engine Testing.—The airscrew, the flat plate air brake, the electric dynamo and the water dynamometer of Heenan and Froude were used for testing aeroplane engines. Later the Escargot reaction torque brake was evolved, corresponding in principle to the Heenan and Froude water brake in that an air fan brake is rotated inside a closely fitted case, into which the air is drawn through central ports and expelled centrifugally through tangential outlets at top and bottom; the engine, mounted on a built-up stand pivoted about the propeller shaft axis, is held and the torque measured with a graduated bar and counterpoise.

To vary the power absorbed at a given speed, the Fell type of Escargot (see figs. 19 and 19a), introducing Butterfly valves in the tangential outlets, was developed late in 1917. Restriction of the air outlet from the Escargot perforce reduces the work to be done by the fan on the air, which tends to rotate with the fan and so increase the speed of the engine to a corresponding degree. A power curve range is thus obtained comparable with that given by the Heenan and Froude brake. The Escargot method provides a ready means of cooling air-cooled engines by taking specified ducts from the outlets to the engine cylinders, whereas the Heenan and Froude brake requires a separate cooling-fan and driving-motor.

In determining the useful H.P. of rotary engines, "windage loss," or the power absorbed by the engine itself, had first to be determined for each type, and then deducted from the total nominal power calculated on the weight bar reading. Originally the bench tests comprised an endurance test of four hours, followed by complete dismantlement and examination for defective parts, excessive wear, reassembly, and final one-hour test, the engine being run throughout at normal speed and at full throttle, petrol and oil consumptions being recorded at both tests. Subsequently all-round experience and increased reliability of materials and their treatment permitted of a reduction of this endurance test, first to three hours, and then to two hours, with a final half-hour test. The engine throughout, save for the last five minutes, was throttled down to 80% of full power at normal speed, to prevent the overheating of and detonation in the relatively high compression engines. Such engines were designed to give full power at 5,000 ft. height rather than at ground level.

Standardization of the actual flow measurement of carburetted jets in place of orifice-diameter calibration made it possible to tune up engines for bench tests on a few minutes' running only. Also standard jets suitable for flight purposes were substituted for bench-test jets before delivery, so that the time of tuning-up on installation of the engine into the aircraft was diminished. In 1916 a petrol-flow meter, whereby the actual flow into each carburettor is indicated, facilitated the determination of petrol consumptions.

Crank-shafts.—The Aero-engine materials were covered by definite specifications originally issued by the Royal Aircraft Factory. The chemical composition was closely defined, heat treatment provided for, and an Izod Impact Test added to the usual tensile test, to give some indication as to the shock-resisting power of the material. The Izod Impact Test, though it does not reproduce the alternating and fatigue stresses of actual running, has proved to be indispensable in detecting steel which has been improperly heat-treated. "Temper brittleness" induced in alloy steels by slow cooling from the tempering temperature, even after correct initial heat treatment, is detected by the 2-3 ft. lb. obtained as compared with the 25-30 ft. lb. with the identical steel if properly heat-treated and quenched after tempering. This brittleness, which obviously unites steels for crank-shaft use, cannot be detected otherwise than by the impact test, since the usual tensile results and micro-structure examination in no way differentiate between the sound and temper-brittleness conditions.

Early in 1914 the British Aeronautical Inspection directorate suggested the following nickel chromium steel for crank-shafts, connect-
ing rods, etc., with good results:—Carbon 35%; Nickel 3.5%; Chromium 0.6–1%.

Difficulties attended the manufacture of crank-shafts for 12-cylinder engines which, in order to reduce the overall length, employed roller main bearings. At first such crank-shafts were produced from billets twisted through 120° at the main journal, which provided only 3 in. in length to which effect the twist, necessitating so high a twisting temperature that no subsequent heat treatment could restore the structure to a uniform and satisfactory condition. The use of a billet of double width involving a twist of only 60° was then tried, with improved but not entirely satisfactory results. Finally such crank-shafts were produced from a billet first pressed or crinkled to a general crank-shaft form to provide a continuous grain flow throughout journals, webs and pins, and finished finally by drop stamping and twisting, where necessary, the main journal through 60° only.

The elimination of all sharp corners, as in keyways and the under-cutting of webs in grinding journals and pins, was found to be of the utmost importance to prevent fatigue failure. Though machining before heat treatment was also required, especially in the rotary single-throw crank with large variations in mass of section, to secure uniformity of condition.

Cylinders.—In 1914 air-cooled cylinders were of mild steel for rotary and cast iron for stationary engines. The steel cylinders were machined from the solid billet; by 1916 forged blanks were used. By 1915–16 cast-iron cylinders were cast from metal pipe and machine-moulded, and a close limitation of chemical composition adopted to secure clean casting of the thin sections, and to overcome distortion and cracking in running. To eliminate casting stresses cylinders were normalised after casting, and set aside for some weeks to "age" before machining.

For water-cooled engines having separate cylinders cast iron (with a sheet-steel jacket pressed to shape, and welded on, or a copper jacket electrically deposited) was used. To allow the jackets to expand, crinkles, both circumferential and round the exhaust valve seatings, and sparking-plug bosses were introduced, as the local expansion of the jacket differs from that of the cylinder when running.

Later, mild-steel cylinders turned from forged blanks were used in lieu of cast iron. Valve pockets, sparking-plug bosses, and thin sheet jackets were then welded on by Vickers in 1909. Two-engine cylinders are also cast together in one block for the sake of the rigidity of the cylinders one to another. At first, following the motor-car practice, cast iron was used for this. Towards the end of 1916, however, aluminium, with its low weight and high heat conductivity, took its place. The first prominent "Mono block" (see fig. 20) comprised a mild-steel cylinder liner complete with head and valve seats, pressed into an aluminium block which took four cylinders, and constituted a core-enclosed water-jacket. The liners were not in contact with the cooling water, and with bigger cylinders overheating and loss of contact between the liner and the surrounding aluminium jacket occurred particularly at the flat head. A natural development, therefore, was to remove the top of the liner, leave it open, and let the aluminium itself form the combustion head of each cylinder. Two difficulties then had to be overcome:—(1) The provision of a gas-tight joint between the top of the liner and the jacket and head; (2) the insertion of rings in the head to form valve seatings. The first was overcome by screwing the liner hard up against the shoulder in the head, and the second (which was achieved without distortion or warping of the seatings) by casting in or expanding-in steel or hard bronze rings. To improve further the cooling of the cylinders, the lower portion of the aluminium jacket in contact with the liners was omitted, the liner being held only by a screw thread of some 1-in. depth at the top and a rubber joint and ordinary lock nut ring at the bottom.

The form of aluminium cylinder head and jacket casting is complicated, and experiments, both as regards method of casting and choice of aluminium alloy, led to the selection of a mixture of 12.5% to 14.5% zinc, 2.5% to 3.0% copper, alloy with very thin aluminium. The pouring temperature is 660°C. The percentage of scrap is high, say, 10% to 15% in the simplest forms of block, and up to 30% or 40% for more complicated designs. To overcome the porosity casters, stone sand-moulding of the interior of the blocks or the application of water-glass under pressure is used.

The Royal Aircraft Factory experiments in 1915 led the way in air-cooled stationary cylinder engines in the use of aluminium heads gilled for cooling, using a steel liner and inserted valve seatings. For rotary-engine cylinders in one instance a thin steel liner was shrunk into a fitted aluminium shell which formed a jacket, the head of steel being secured to the liner with a plain metal-to-metal joint by bolts from the head to the crank-case, thus securing the cylinder as a whole.

Cylinders of all types before erection on engines are tested internally to 450–500 lb. hydraulic pressure, and for the jackets to 30–40 pounds.

Connecting Rods.—Connecting rods, as regards material, followed crank-shaft practice in the standardisation of plain nickel chrome steel, heat-treated to give 50–60 tons’ tensile strength.

The 6-cylinder and early 8- and 12-cylinder types conformed to motor-car practice in the use of solid "H" section shanks and white-metal big-ends, without a bronze bush, the cap being held usually by four bolts or studs. To reduce the crank-shaft length of certain "V" type engines the connecting-rods on one side of the engine were provided with lugs to carry a wrist-pin, this wrist-pin, on one side of, and parallel to, the big-end bearing, carrying the auxiliary connecting-rod. Alternatively to the same end a pair of rods superposed. In one case, a hollow circular sectioned shank carried an integral big-end, white-metalled internally and externally, the second rod, being fork-ended, oscillating on the sleeve formed by the first rod. The comparatively thin and flexible section of the inner rod sleeve, however, enhanced the difficulty of white-metalling and led to cracking in running.

A further development therefore (of square hollow sectioned shank) provided a bronze shell rigidly gripped by the forked ends of the outer rod, while the inner rod oscillates on the middle portion of the shell, which is white-metalled internally to provide the main big-end bearing, as shown in fig. 21.

Fig. 21.

Connecting-rod of rotary and radial engines consist usually of one master rod, ball or roller-bearinged, with the big-end enlarged to form circular lugs to secure wrist-pins carrying the plain or auxiliary type of shank with the remaining originally. One exception provided a big-end consisting of a separate lead bronze shell (in two halves bolted together) mounted on ball bearings and provided on the inside with white-metalled concentric grooves in which oscillate the concentrically formed shells of the connecting rods.

Initially, the ordinary small-end bronze bush system with gudgeon pins fixed in the piston was used. Later, variations with loose bushes and loose gudgeon pins were developed, the pins in the latter being secured endwise in the piston by wire circlips let into grooves on the outside edges of the piston bushes.

Rough machining before heat treatment is necessary on the rotary type of re-rod where a large big-end mass and a comparatively small stem section, to secure uniform structure and freedom from quenching cracks. The elimination of all sharp corners and abrupt changes of section is essential.

Main Bearings.—Ball, roller and white-metal bearings are to be found in various types. The two former permit of high loading and reduce the length of the engine (bearing loads approximating to 100 lbs. per h.p., and max. continuous bearing load of 450 lbs. per in. bore, with the rest of the engine under service conditions). White-metal main bearings, usually bronze shell, are secured either by separate loose caps bolted on or studded to the top half crank-case or, as in German practice, by the bottom half crank-case itself, which carries the lower halves of the whole of the crank-shaft bearings; this adds to the rigidity and general strength of the engine, but increases the difficulty of production and fitting.

Fig. 21. valve block, which was a trouble, was almost eliminated by the standardization of valve steels and by stamping the valves
so that the grain flow in the valve head swept continuously and uniformly from the rim into the throat and stem, thus providing strength to resist shear at all points of the head. The original practice, before bulk production warranted the use of stampings, had been to turn valves from the solid bar, a procedure which gave in the head a grain flow parallel to the stem.

For exhaust valves a steel having 14% tungsten and 3%-5% chromium is necessary in certain of the larger "stationary-type" engines, with a weight of 9-12 lb. per H.P. Benz, weighing 4-5 lb. per H.P., has been successful in using such steels for inlet valves, but, for economy of such high-grade materials, a plain nickel steel is used with great success. (R. K. B.-W.)

V. AERO ENGINES

Historical Résumé.—For many years mechanical flight was delayed for want of a light engine, and indeed from the first flight to the present day (1921) the aeroplane was ahead of its prime mover. Flight should have been possible in 1901 when Manley, in the United States, built Air S. P. Langley a four-cylinder radial petrol engine developing 52 H.P. and weighing only 2-9 lb. per H.P. By bad fortune this engine was, however, never used in flight until 1914, when it was mounted in the Langley aeroplane for which it was intended.

For their first flights in 1905, the brothers Wright built a four-cylinder car-type engine of 12 H.P., weighing 12.7 lb. per H.P. By 1905 it was improved to 19 H.P., with a weight of 9-5 lb. per H.P. and, as redesigned in 1908, gave 35 H.P. and weighed 5-5 lb. per H.P.

The engine proper dates from about 1900, and the progress made is traceable reliably by the results of competitive tests held from time to time. Such tests were carried out in France, 1900-11-13, in cooperation with La Ligue Nationale Aéronaute and the Auto Club de France; in England in 1909-12-14; in Italy in 1913, and in Germany in 1912-4.

A certain section in England centred its hopes erroneously on the use of very small engines. A. V. Roe made the wonderful achievement of flying an aeroplane with only 0-10 H.P. in 1909. The Alexander prize of 1911 at first stipulated for engines of only 25 H.P. This was increased by the Advisory Committee at the request of the Department of the Army Aircraft Factory to admit "40 to 75 H.P." and was won by 24 hours' continuous running of a 50-60 H.P. Green sent in on Sept. 11 1911. This engine weighed 206 lb. complete, and developed an average of 53-5 H.P. The British Government competition of 1914, although won by a 110 H.P. Green engine, was chiefly useful in showing the merits of the 100 H.P. Gnome and the 90 H.P. R.A.F. Both of these did yeoman service in the war, but soon proved to be too small.

In Germany, the development of the airship led to the earlier study of larger aeroplane engines, although the German competition of 1911 required only 4-2 H.P. per lb. The importance of the aeroplane in war service gave an immense impetus to engine development along two main lines: (a) An extensive development of high tensile steels and aluminium alloys, and a more scientific use of the materials, led to a diminution of the weight; (b) attention to detailed design, guided by scientific investigation, greatly increased the mean effective pressure developed in the cylinders and the thermal efficiency. The speed of rotation was also increased so that output was augmented, while at the same time fuel consumption was reduced.

Modern aero engines may be divided into two classes:—(a) Engines which are developments of the motor-car type, i.e., all the water-cooled vertical, Vee, and broad-arrow engines; (b) types designed specially for aerial flight, i.e., the radial rotary engines and the air-cooled Vee engines.

The rotary air-cooled type, which was one of the earliest of these, was almost entirely due to the French; e.g. the Gnome, Le Rhone and Clerget engines. In this type minimum weight was the objective. The arrangement of the engine, with its cylinders radiating star fashion in one plane and operating on a single crankshaft and crank-case of minimum dimensions and accordingly giving a motor of extremely light weight, to increase the cooling by air draught, and save the weight of a fly-wheel, the cylinders were made to rotate round the crank-shaft, which was fixed. Weight was economized by making the cylinders of steel, with very thin walls, and the difficulties due to distortion of such thin cylinders with heat were ingeniously met by using a brass obturator ring, as substitute for the cast-iron piston rings which are universal in other engines.

In 1909 a number of rotary engines of powers ranging from 30 to 100 H.P. were available. Of these the 100 H.P. Gnome was the most powerful. In 1913 a 14-cylinder Gnome of 160 H.P. was launched, and on a British army aeroplane achieved the fastest flight up to that time, namely 130 m. per hour. At the outbreak of war in 1914, the 100 H.P. Monosoupape Gnome, at a slightly later stage the 110 H.P. Clerget and the 100 H.P. Le Rhone came into general use, and the 160 H.P. Gnome, was, unfortunately from the war fighter's point of view, discarded on the score of complication. In France in 1917 a higher-powered Monosoupape developing 350 H.P. was put into commission, while in Great Britain the BR1 and the BR2 rotaries, developing respectively 150 and 220 H.P., were produced. Including the propeller boss the later Mono-Gnome weighed 2.05 lb. per H.P. and the BR2 2.21 lb. per H.P.

In 1914, and indeed at a later stage, none of the rotary engines were quite satisfactory; the type suffers from certain inherent disadvantages. It is liable to the distortion and overcooling of its cylinders; the earlier examples required special precautions against catching fire; its petrol and oil consumptions are high; and it requires frequent dismantling and overhauling.

In spite of this the best of these rotaries formed the basis on which European air experience was founded, and as recently as 1912 the best aeroplane engines (from the point of view, be it understood, of the aeroplane's performance, which is dominantly a matter of weight) were probably the Gnome rotaries weighing from 30 to 35 lb. per H.P. At this time long-distance flights were exceptional and therefore their large fuel and oil consumption was not so serious. Throughout the war, and especially in its earlier stages, they gave their service in machines of the single-seater high-speed class, in competition with the heavier water-cooled vertical engines on which the German air service relied almost entirely.

When the distance of flight was extended, the water-cooled car-type engine came to the front partly because the smaller weight of fuel to be carried compensated for the greater weight of the engine itself, and partly because it was at that time more reliable. The following table shows the total weights of engines, fuel and oil, for flights of different duration, in the case of a typical air-cooled rotary engine weighing 35 lb. per H.P. and consuming 1.10 lb. of fuel and oil per H.P. hour, and of a water-cooled engine weighing 40 lb. per H.P. and having a total consumption of 0.55 lb. per H.P. hour.

For longer flights than 3½ hours the water-cooled engine is here shown to involve a smaller gross weight.

It was largely emulation of the rotary which forced the pace of the progress on the car-type engine. This led to the replacement of cast iron by sheet metal for water-jackets; to the use of thin steel instead of cast iron for cylinder barrels and of aluminim for cylinder-head castings; and to the use of two, and in some cases three, rows of cylinders operating on a single crank-shaft and mounted on a common crank-case. The use of steel or aluminium alloy instead of cast iron for the pistons had been initiated in experiments for motor-cars. In some few cases air-cooling was adopted, e.g. in France the 70 H.P. eight-cylinder Vee Rensolt of 1912, and notably in England the 90 H.P. eight-cylinder Vee R.A.F. of 1913-4, and the 140 H.P. twelve-cylinder Vee R.A.F., all of which had cast-iron L-headed cylinders. The last-named engine weighed 40 lb. per H.P. and gave excellent service during the war.
Still the car engine of given cylinder capacity remained appreciably heavier than the contemporary rotary, until careful studies in 1916-17-18 were made to increase the output per unit of cylinder volume, and the thermal efficiency.

The volumetric efficiency was increased by improving the design of the inlet pipes, valves, and valve gearing, and the combustion space of the cylinder. The thermal efficiency and the mean effective pressure were increased by augmenting the compression. Since high compression is only practicable with a compact and symmetrical combustion chamber the L-headed cylinder was replaced by the overhead valve-cylinder. Moreover, since high compression necessitates good cooling of the cylinder, the water-cooled engine gained a distinct relative advantage over the earlier air-cooled engines which were, in general, inadequately cooled. As a result of these steps in the detail design, the brake mean effective pressure was raised from the 75 to 95 lb. usual on cars, to as high as 130 lb. per sq. in. in the best modern aeroplane engines, while at the same time the petrol consumption was reduced to approximately 0.45 lb. per B.H.P. hour, a value some 40% better than that of the average car engine.

In many cases the output was also improved by increasing the speed of the engine. The speed of the rotary engine was limited to about 1,200 revolutions per minute, by the stresses due to centrifugal force. In the fixed cylinder engine, however, much higher rotational speeds could be adopted by attention to the balance of the moving parts, and to the design of the bearings. These speeds now range from 1,400 to 2,100 revolutions per minute, reduction gears being used for the airscrew drive in the case of the larger and less rapidly flying aeroplanes.

The resultant weight economy was considerable. Thus the 450 H.P. Hispano-Suiza water-cooled Vee, rotating at 2,000 r.p.m., weighed only 1,300 lb. per H.P. and the 450 H.P. Napier "Lion" of 1921 only 1,890 lb. per H.P. In each case these weights include that of the propeller boss, but not that of the radiator and its water, which would add approximately 0.55 lb. per H.P.

These advances in the car type of aeroplane engine were accompanied by improvements in the specialized type. In 1912 the radial engine with fixed cylinders was represented by a few examples of the 9-cylinder, water-cooled "Salmon", developing 110 H.P., the 6-cylinder, water-cooled "Lavator" developing 80 H.P., and the 6 and 10 cylinder, air-cooled "Anzani", developing 60 and 120 H.P. are among the most noteworthy. The Salmon was developed at a later stage as a 14-cylinder, two-row engine of 200 H.P. and the Anzani as a 20-cylinder, four-row engine of 200 H.P. These engines were French, but since 1914 British designers have greatly advanced the science of the air-cooled engine.

The fixed radial engine has a number of features of superiority over the rotary. It enables a normal type of carburettor and of piston to be used; it eliminates the large windage losses; while since the cylinders are not exposed to centrifugal stresses aluminium alloys can be used. This light and highly conducting metal has greatly helped air-cooling. Owing to the greater ease of installation of the air-cooled engine in an aeroplane, the absence of a fragile radiator liable to freeze on descent from great heights, as well as to its adaptability to work in the tropics, much attention was paid during the war to the design of air-cooled cylinders. A composite construction using aluminium alloy for cylinder heads was evolved at the Royal Aircraft Factory, Farnborough, between 1915 and 1921, with the result that air-cooled cylinders became available which, for diameters up to 6 in. and up to 50 B.H.P. per cylinder, give an output and fuel-consumption of similar order to those from the best water-cooled cylinders.

No air-cooled engine with these large cylinders reached the stage of production in quantity during the war. A number of British radial engines were, however, developed in 1918, and of these the "A.B.C. Dragonfly," having nine steel cylinders, giving 300 H.P. and weighing 2-22 lb. per H.P., and the 450 H.P. "Cosmos Jupiter," having nine steel cylinders with an aluminium patch containing the inlet and exhaust ports bolted to each head, and weighing 1-42 lb. per H.P., are of mention.

As compared with these it will be recalled that the 150 Mono-Gnome of the same date weighed 2-03 lb. per H.P.

A 12-cylinder Vee experimental engine with aluminium cylinders was built at the Royal Aircraft Factory in 1916-7 and gave excellent results in flight and on the test bed. This developed 210 H.P. and weighed 3-5 lb. per H.P.

Prior to 1914 the American aero engine was mostly of the radial type, and was outdistanced during the first two years of the war by the more intensive development in those countries actively engaged. At that time the 160 H.P. Curtiss was probably the most outstanding engine in America, and when the United States declared war in 1917 her need for high-powered aeroplane engines became acute. In May 1917 it was decided, in conference with the Allied Mission in the United States, to design and build the Liberty engine, of which an 8-cylinder model was completed for test on July 3 1917. This was not put into production, as advances from France indicated that demands for increased power would render it obsolete before it could be produced in quantity. Efforts were then concentrated on a 12-cylinder model, the first of which passed its 50-hour test on Aug. 25 1917. This engine is a water-cooled Vee, originally developing 450 H.P. and weighing 2-6 lb. per H.P. More recent improvements have increased the output to 510 H.P. and reduced the dry weight per H.P. to 2-75 lb. or about 2-3 lb. with cooling water and radiator.

The progress in the average aero engine in service between 1910 and 1918, in power, weight, and efficiency, is shown in the following table. The main details are abstracted from the report of the American National Advisory Committee for Aeronautics in 1918:

Since the water-cooled engines cannot function without radiator and water, an addition of 0.55 lb. per H.P. has been made in their case to render Table A comparative. The weights after deduction of 0.55 lb. are actual measurements, and include those of the propeller boss and of the gear, if any. In cases where the respective makers produce a series of engines of different powers, only representative examples have been quoted.

During the latter part of the war, the demand for engines of large H.P. for bombing aeroplanes and dirigibles led to the production of many experimental engines, which were available by 1921, e.g. the 800-900 H.P. Sunbeam Coatalen, the 850 H.P. Fiat, the 1,000 H.P. Lorraine Dietrich, and the H.P. "Napier" "Cosmos Jupiter." Types of Engines.—Of the total heat from the fuel, 25% to 35% passes through the walls and piston and must be dissipated by water-cooling or direct air-cooling if the normal operation of the engine is to be maintained.

Water or air-cooling have their respective advantages and disadvantages.

For the water-cooled engine is claimed:—

"The water-cooled cylinder-wall temperature; a reduced tendency to the burning of exhaust valves and pistons; and more effective lubrication.

</table>

(2) A greater uniformity of temperature throughout the cylinder, and therefore less tendency to distortion.

(3) Generally, greater reliability and higher efficiency.

These advantages could justify be claimed over the earlier types of air-cooled engines; to-day they are less clear. Thus the first claim is only justified where great attention is paid to the design and arrangement of the jacket and circulating systems. Measurements confirm claim (2), but also show that the lack of uniformity is not necessarily a serious matter, while troubles from overheated exhaust valves have recently been more prevalent on water-cooled than on the modern air-cooled type.

For the air-cooled engine we claim:

1. Smaller weight per H.P. of the complete power unit.
2. No danger of water freezing on gliding from high temperatures, when standing.
3. Reduced vulnerability in war service and easier installation.
4. Special adaptability for use under widely differing atmospheric temperatures, and for the tropics.

(5) Better adaptability for application of some supercharging device to give constant power at heights.

Claim (1) is a matter of demonstration, the usual weight allowance for water-cooling being 6 lb. per H.P., while the very best is 0.4 lb. per H.P. Claims (2) is admissible to the extent that if freezing be prevented by the use of some other liquid, such as a mixture of alcohol and water, the alcohol evaporates unless the temperature of the fluid is kept below about 70° C. which increases the radiator size.

There is undoubtedly a future for the air-cooled engine of the fixed-cylinder type up to a certain size of cylinder. What this limit of size may be is not known at present. Cylinders of 8-in. bore by 10-in. stroke development over 100 H.P. have been made and proved to be possible, and investigations on cylinders up to 10 in. diameter are in progress. Twelve 6-inch cylinders would give 960 H.P., a useful size at present, and an 800 or 900 B.H.P. air-cooled engine is certainly feasible.

**Design of Air-Cooled Cylinders.** The use of aluminium alloy for the cylinder heads has largely conduced to these results. In a normal design the middle portion of the head is the hottest part because the flow of cooling air is checked at this point by impeded by the inlet and the exhaust valve ports and valve gear. Most of the heat has to be conducted outwards till dissipated from the periphery of the combustion head, and the aluminium alloy effects this well, both because its conductivity is 3.5 times greater than the steel, and because being 0.4 of the density of steel it may be used in ample thickness.

Such a cylinder must be of composite construction, since the valve seats and the working surface of the cylinder barrel must be of some harder material than aluminium. The valve seats may consist of rings of steel or of bronze, and these may be either cast or expanded into position. Tests appear to favour a steel barrel with integral cooling fins, screwed into an aluminium head for diameters as large as eight inches.

**Arrangement of Cylinders.**—Aero engines may be subdivided according to the arrangement of their cylinders, into the following types:

1. Single line engines suitable for water-cooling.
2. Vee engines suitable for water-cooling.
3. Broad arrow engine suitable for water-cooling.
4. Radial engines—fixed cylinders—air-cooling.
5. Rotary engines suitable for air-cooling.

The general arrangement of these types is shown in Fig. 22.

The straight line engine (a), with six or eight cylinders in line, offers a low head resistance and is accessible. On the other hand its fore-and-aft length is large. The crank-shaft and crank-case are long, and hence the type is heavy.

In the Vee type engine (b) two lines of cylinders are used inclined to each other to form a Vee in elevation, and the corresponding port and starboard cylinders operate a common crank-pin. Weight is saved on crank-shaft, casing, and valve gear.

In the Broad Arrow (c) three lines of cylinders are used as above with further weight saving.

In the Radial engine (d) economy of crank-shaft and case is carried to its logical conclusion. The cylinders are mounted in one plane at equal angular intervals around the crank-shaft. All the connecting rods operate on a single crank-pin. The small fore-and-aft length of the engine helps the aeroplane designer but its considerable diameter may hamper him.

To obtain explosion impulses at equal intervals throughout each revolution an odd number of cylinders must be used, the usual number being seven or nine. Where a larger power is required two rows of cylinders may be used, operating on a throw crank-shaft. The radial cylinders may be stationary or rotating. In the latter case the air screw is mounted on a continuation of the rotating crank-case. The rotating cylinder engine is not quite unsuited for water-cooling. Although the radial engine with fixed cylinders is not well
adapted for water-cooling, engines of this type have been built and operated successfully. Among these is the recent 300 H.P. 9-cylinder Fiat, weighing 17 lb. per H.P. The difficulty of arranging the water circulation so as to avoid danger of air locks in the inverted cylinders is, however, appreciable, and the head resistance of the completed engine is large. For these reasons there is not likely to be any great future for the water-cooled radial engine on aeroplanes of present types.

**Installations of Air-Cooled Engines.** Some form of cowling is needed to distribute the air evenly over the various cylinders, and the success of a Vee engine depends largely on the cowling, whereas even air-cooling is more easily obtained on a "radial." With rotary engines the cowling is not as good as might be expected from the high peripheral velocity, and the windage losses, even with a cowling, amount to some 10% of the total power developed.

In these engines the air-petrol mixture is led through the hollow crank-shaft to the crank-cases. In the original Gnome engine automatic inlet valves fixed in the piston heads and opened by the suction on the inlet stroke admitted the charge. These valves were light, often broken, and were inaccessible.

In the Monocoup Gnome the valve in the piston is eliminated and a mechanically operated valve in the cylinder head is used. This serves as an exhaust valve, but, instead of closing at the end of the exhaust stroke, it remains open for a part of the inlet stroke and then admits air to the cylinder. When it closes, the further motion of the piston produces a partial vacuum in the cylinder, until, near the end of its stroke, the piston uncovers a ring of openings in the cylinder walls communicating with the crank-case. The fuel jet is adjusted to give a mixture too rich to be explosive, and this mixture enters into the cylinders and mixes with the air admitted through the inlet valve to form an explosive charge.

Other modern rotary engines have mechanically operated inlet and exhaust valves, with which efficient valve timing becomes possible. The mixture in the crank-case then passes into a circular box fixed to the rear of the crank-case and rotating with it, whence it is led by inlet pipes to the cylinders in the ordinary way.

These methods of mixture supply, though crude, gave the rotary engine the advantage of having a fuel supply adjustable by hand to suit the air density when flight at great heights first became important. On the other hand, the none rotary engines, fitted with normal carburetters, received a mixture too rich for efficient operation at considerable heights. To obviate this, automatic carburetters controls had to be devised; but pending this the rotary engine had a distinct advantage for high flying.

The lubrication of the rotary engine is peculiar to the type. All oil in the crank-case is thrown centrifugally into the cylinders, and since there cannot be drained out, cooled, and circulated again as in fixed-cylinder engines, but must be discharged through the exhaust valves. Consequently the oil consumption is high. Moreover the lubricating oil must be insoluble in petrol; thus that castor oil is necessary.

The power of the rotary engine falls off more rapidly with height than that of the fixed-cylinder engine if the latter has a suitably controlled carburettor, and at a height of 15,000 ft. the difference in horse-power is about 10 per cent.

**The Differential Engine.**—For large powers, each of the two types of radial engine has its own peculiar limitations. In the fixed radial the fly-wheel effect is small, while it becomes difficult to design an engine exceeding about 400 H.P. on a single crank because of the expenditure involved on the complex system of oiling and lubrication. In the rotary radial this difficulty is less, but windage losses, centrifugal stresses, gyroscopic effects and valve-gear difficulties are encountered.

The "differential" engine has been proposed to combine some of the advantages of both types. Here the cylinder ring groove is in the direction and the crank-shaft in the opposite direction at the same speed. In this way the big-end loading may be kept within reasonable limits, while the gyroscopic effect is negligible; centrifugal forces and windage losses are comparatively small; and the speed of rotation is low enough to permit an efficient airscrew to be fitted.

If the big-end loading be taken as the criterion, the power of the differential engine is about 30% greater than that of the fixed radial engine, or, deducting the windage loss, about 26 per cent. Whether this advantage outweighs the complication in design, remains to be proved.

**Cycle of Operation.**—All aero engines are of the single-acting type in which driving impulses are received on one side only of the piston, and in the majority of engines the four-stroke cycle is adopted. The two-stroke cycle has not hitherto been adapted successfully to the aero engine, owing to its comparatively inefficient high-speed engine which requires to operate over a wide range of speeds.

A six-stroke cycle is in the experimental stage. It consists of the four-stroke cycle with the addition of a suction and exhaust stroke. The first suction stroke draws in a charge which is compressed into an auxiliary reservoir on the succeeding stroke. The next stroke is also a suction stroke which draws in another fresh charge. On the end of this stroke a valve opens and allows the cylinder the charge compressed during the preceding stroke, and during the succeeding stroke both charges are compressed into the combustion space and fired. In this way a charge of double weight is obtained and the mean effective pressure during the expansion stroke is twice as great as in the four-stroke cycle. The mean effective pressure over the whole six strokes of the cycle is thus 33% greater than the mean effective pressure over the whole four strokes of the ordinary cycle. Since the explosion pressures are approximately twice as great as in the four-stroke cycle the cylinder construction is heavier.

For evenness of turning moment, the two-stroke is better than the four-stroke, and this than the six-stroke cycle.

In each of these cycles the mixture is drawn into the cylinder, compressed, burnt at constant volume, and expanded to the same volume as before compression. The theoretical efficiency of this cycle is given by the expression 1 - (1/γ) γ-1 where γ is the ratio of the volumes before and after compression and γ is the ratio of the specific heats of the working fluid at constant pressure and constant volume. This is known as the air standard efficiency. It assumes that the specific heat is constant at all temperatures, and it applies to the case, with a given ratio of heat to the walls of the cylinder, in which case the value of γ is 1-460.

Taking into account the variation of specific heat with temperature, the appropriate value of γ in this expression becomes 1-295 and except for losses of heat to the cylinder walls and piston, the efficiency of an aero engine should attain the values corresponding to its compression ratio, which are:

<table>

These figures indicate the importance of a high compression ratio. This is particularly important in the case of an aero engine, since the drop in power with height diminishes as the compression ratio is increased.

It is, however, set to the compression ratio in practice by the tendency of a petrol-air mixture to detonate when compressed to a high pressure and temperature. Such a mixture has a "spontaneous" ignition temperature corresponding to any definite pressure, at which it will detonate, and should this combination of temperature and pressure be attained in operation it is apt to cause overheating of the sparking plugs and to lead to general overheating of the cylinder and engine to produce power prudently.

The tendency to detonation depends largely on the design of the combustion chamber. It is less where this is compact and symmetrical than where it contains pockets as in a cylinder of the L-head pattern. The position of the sparking plug and that of the fuel in the cylinder determines the position of the spark plug and, also the composition of the fuel. The addition of benzol or benzene to petrol enhances a higher compression ratio to be used, but owing to the comparative high freezing point of benzol not more than about 25% can be used in admixture with petrol, for use at great heights.

By attention to design it is now found possible to use compression ratios as high as 5-6 when using petrol as a fuel, and as high as 6-5 when using petrol-benzol mixture. With such compression ratios,
fuel consumptions in the neighbourhood of 0·45 lb. per B.H.P. hour may be attained.

**Supercharging for High Flying.**—Since the power is proportional to the weight of petrol-air mixture taken in per cycle, and since this weight depends on the density of the surrounding atmosphere, the power falls off with the height reached. This can be provided by a supercharger, sensibly proportional to the atmospheric pressure. The law of variation with atmospheric density varies slightly with the type of engine, but may be taken approximately as

\[ B.H.P. = \frac{\rho}{\rho_0} \cdot \text{constant} \]

where \( \rho \) is the density, and \( \rho_0 \) varies from 1·1 to 1·3, increasing slightly with the height. At different heights developed by a 200-H.P. engine at a constant engine speed is thus approximately as follows:

<table>

Since the resistance to the motion of an aeroplane diminishes directly as the air density, other things being unchanged, and the speed of a 200-H.P. engine at a constant engine speed should only diminish slightly with an increase in height. This diminution in speed is, however, rendered more pronounced by the fact that the angle of incidence of the planes requires to be increased to get the same lift in the air of reduced density, and this increases the head resistance.

Therefore the speed of the aeroplane is reduced in a much greater degree, since the energy to be expended in lifting the dead weight, the weight of the body, and the given height is independent of the density, and remains constant at all heights; and at some definite height, depending on the design of the aeroplane and the power of the engine, the power is no longer sufficient to lift the body, and when flying at the minimum safe speed of the aeroplane with the increased angle of incidence of the planes, without leaving any surplus lifting capacity. This height is termed the "ceiling" of the plane.

Any device which would enable the power of the engine to be main- tained at height would not only increase the level speed, but more especially the rate of climb and the height of the "ceiling" of the plane. In the first the engine is fitted with differential pistons. Air is drawn into the space between these on the outside stroke of the engine, compressed on the return stroke, passed through a cooler, and forced into the cylinder through a series of ports uncovered by the piston slightly before the end of the suction stroke. By this method the weight of mixture in the cylinder is increased. The degree of 'supercharging' may be adjusted to suit the design of the engine. The plan is, however, successful only if the increased pressure is applied directly to the cylinders which are thus fed with mixture under an increased pressure. The system is, of course, an added complication and involves the very high risk of leaks and breakages. The induction system is under pressure, any leaky joints will derange the operation of the engine, and lastly, since the speed of the blower is constant at constant engine speeds, the amount of supercharging falls off with increased height. Therefore, near the ground, air must be blown to waste through a bypass valve.

In the third system the engine exhaust is discharged through a single-wheel high-speed impulse turbine of the Kakea type. This turbine is direct coupled to a centrifugal blower feeding the car burreter, and delivers sufficient air to the engine to maintain its power at all heights up to 15,000 feet. This method is partially automatic in that if the pressure in the induction pipe is maintained constant, the pressure of the exhaust gases will be constant, and since the pressure on the exhaust side of the turbine diminishes with height, the pressure available for driving the turbine increases with height. The pressure in the exhaust side of the cylinder, and hence the induction pressure is under pressure, any leaky joints will derange the operation of the engine, and lastly, since the speed of the blower is constant at constant engine speeds, the amount of supercharging falls off with increased height. Therefore, near the ground, air must be blown to waste through a bypass valve.

The increase in economy of the installation, the work thrown on the pilot, and the risk of breakdown will all retard the introduction of such schemes. Moreover, the additional weight may alternatively be disposed of by increasing the size of the cylinders, leaving the crank case and crank-shaft, etc., sensibly unaltered. Such a "light" engine would not withstand being opened out fully near the ground, and special precautions would require to be taken to prevent this happening. At high altitudes, however, it can be fully opened, and an increased power corresponding to its increased cylinder diameter taken advantage of. Such a unit has the advantage of simplicity. Many of the latest and most powerful engines are really in a modified degree "light" engines, in that they cannot be run for more than a very few minutes at all, due to their size.

One method of reducing the drop in power with height is possible. One such method is to design the engine with a compression ratio too high to permit of ground operation, and to reduce this ratio by means of a blower, thus giving it a high efficiency at high altitude. As the height increases the inlet valve would be closed earlier in the stroke until, at some predetermined height, normal timing would be attained. A second method which has been suggested consists in the reduction of the proportion of the air in the cylinder with the working mixture. This reduces the tendency to detonation and enables a higher compression ratio to be adopted than would otherwise be permissible. As the height increases the proportion of the fuel as would be reduced, until, at the predetermined height, the engine would be working on a normal mixture.

**Engine Starters.**—The operation of starting an aeroplane engine has already been discussed, and there remains to be considered the starting facilities for the engine. Tests show that in an average engine the power is sensibly proportional to the atmospheric pressure. The law of variation with atmospheric density varies slightly with the type of engine, but may be taken approximately

\[ B.H.P. \propto P^n \]

where \( P \) is the density, and \( n \) varies from 1·1 to 1·3, increasing slightly with the height. At different heights developed by a 200-H.P. engine at a constant engine speed is thus approximately as follows:

<table>
<thead>
<tr>
<th>Height, feet</th>
<th>0</th>
<th>5,000</th>
<th>10,000</th>

The most usual starting system consists of a supplementary magnet placed in the cockpit and rotated by hand by the pilot. If this system fails, or the crank-shaft is at fault, it is usual to have a compressed-air starting system. For success one or more of the cylinders must contain an explosive charge and therefore the crank-shaft is rotated slowly by hand, drawing a charge of petrol vapour from the carburiser as in normal operation. As soon as the engine is running, starting is facilitated by admitting coal gas or hydrogen into the induction pipe from a small container, while the crank-shaft is being rotated.

One modern device, still (1921) in the experimental stage, consists of a small two-stroke single-cylinder engine which is started by hand and drives a compressor which draws an explosive mixture from its induction pipe and forces it through the correct cylinders of the main engine. This charge is then fired in the usual way.

**Future Development of the Aero Engine.**—The development of the aero engine must increase its reliability, its useful life, its efficiency and its output in horse-power per unit weight, especially at height. Experience gained in the operation of existing types, by a process of survival of the fittest, slowly leads to the elimination of those which are in any way unsatisfactory for breakdowns. The reduction of bearing loads and the improvement in bearings, increased perfection in balancing, better design of valve springs and of valves, design of pistons and piston rings and of lubrication systems, will all add to the useful life, while improvements in carburisation, in cooling and lubrication, induction systems, and in sparking plugs, will lead to increased reliability of operation. Efficiency will be enhanced mainly by improvements in the design of the induction systems, and use of such fuels as will admit of higher compression pressures.

It seemed possible in 1921 that the Diesel cycle might be developed for aero-engine work, and the Junkers engine of this type has since been developed and put into practical work. In view of the heavy cylinders required a sufficiently light Diesel engine, however, appears to be very difficult of attainment. Failing this, the direct injection of petrol into the cylinder by means of a special compression stroke, using moderate compression ratios, may have possibilities. This is a modification of the method used in the early Antoinette engine, where fuel was injected by a pump into the inlet pipe of each cylinder. The method has the advantage of eliminating the carburettor and induction system and, in theory, of enabling a uniform mixture to be given to all the cylinders. Promising experiments on single-cylinder engines were in progress in 1921.

Of the existing designs in 1921 there appeared to be scope for an engine working on the two-stroke cycle, and for a double-acting line engine with cylinders in tandem. It is true that attention had already been paid to the tandem engine, and that experiments had been made with various designs. These designs have already been shown to result. Still, many of the initial difficulties had been surmounted, and there was every reason to hope that a successful design would ultimately be evolved. Such an engine would have excellent prospects of fulfilling the requirements of the future, and at present the dream of the aero-engine designer. In view of the immense progress in the design of aero engines during 1921-21, it seemed probable that the aero engines of the future might well show as much improvement as was possible of that already achieved with the machinery to which the early fliers entrusted their lives.

(A. H. G.)

**VI. AIR NAVIGATION.**

**Historical.**—Navigation is the art of selecting the course which a craft should take in order to proceed from any one position on the waters to any other. For guidance in the building-up of air navigation centuries of experience of the sister art of...
sea navigation may be drawn on, and much of this experience is capable of direct application to the air. The earlier forms of marine navigation were of a rudimentary type and would now be included in the general term "pilotage." Whenever they could manage to do so the primitive sea voyagers were careful to keep in sight of the coastline, so that even a rough map sufficed to enable the position of the ship to be noted. The great voyagers of the middle ages were bolder and depended no longer on mere pilotage methods; then it was that scientific navigation had its birth. The compass came into uso in Europe about the 14th century, and by its means, combined with a rough measurement of the speed of the craft through the sea, it was possible to keep a reckoning on the chart—called a "dead reckoning," or briefly D.R.—of the position from day to day. This allowed nothing for drift due to tides or river or leeway, but since in the early voyages these were quite unknown in amount no allowances could be made. Experience showed that the D.R. position thus obtained was often considerably in error, and some check upon it became very necessary. For this the simple cross-staff and the astrolabe were employed. With these instruments a rough measurement of the altitude of the sun at midday, or of the pole star at night, enabled the latitude to be determined to perhaps half a degree, or 30 nautical miles. But a simple latitude observation like this did not suffice to ascertain the ship's position, since it merely gave the information that it must be somewhere on an east-west line drawn so many degrees N. or S. of the equator. If the course were N. or S., this measurement gave the run, but no check on the estimated course; whilst if the course were E. or W., the latitude measurement gave no information as to the run.

Later on, when better instruments were available—the introduction of the Hadley sextant in 1731 marked a very real advance—methods were adopted to enable longitude as well as latitude to be measured, but the necessary calculation of lunar distances was troublesome, and it was not until the perfection of the marine chronometer and the speed of sailing vessels that this branch of navigation became open to the average sea navigator to work out his longitude as well as his latitude, and so obtain a check on both run and course.

Experience with air navigation has followed a generally similar path; compressed of course into a very few years. When air craft were first navigated they followed pilotage methods only; the earth was continuously, or almost continuously, in sight, and the position from time to time was ascertained by the recognition of landmarks, or, where these were scarce, by a system of dead reckoning based on the compass course and the speed of the ship. There were however, areas on an east-west basis between sea and air conditions. Currents in the sea rarely exceed a few knots, but in the air are quite commonly of 20 knots, velocity, and may be even four or five times as much; moreover, whilst the former may be charted the latter cannot. This would tend to make air navigation more difficult, but its effect is mitigated by the fact that the air ocean has the great merit—of being transparent (except for occasional cloud sheets) and of enabling the direction and course of air currents to be measured by watching the apparent motion of objects on the earth's surface. A wind of 50 knots opposing an air craft having a speed through the air of 100 knots will reduce its speed over ground by one-half, while if favouring it will cause the ground speed to exceed the air speed by 50%; neither, however, will cause any apparent sideways drift of the craft. If, in either of these cases, the speed over the ground be measured in some convenient way, it is possible to determine both the velocity and direction of the air current, i.e. the wind. A similar but slightly more troublesome measurement gives the wind velocity, and direction, when the flight is oblique to the wind. This ability is not shared by the sea navigator, who cannot see the bottom of the ocean on which he sails, but he has instead to assume the accuracy of the information given on his charts and in his sailing directions.

The fact that an aircraft, when flying with the wind, may have a ground speed of as much as 150 to 200 knots, makes it essential to determine the position with rapidity. An observation which took 10 minutes to reduce would afford information of a position some 30 nautical m. to the rear. Hence speedy methods are required for real-time reckoning; it is the essence of a vital note and shouldev, and the extensive field of view—much less accuracy of position-finding is required in the air than at sea. An accuracy of determination of 10 m. suffices for almost all air purposes, whereas the sea navigator aims hopefully at "an accuracy within a mile or less."

Dead Reckoning.—Hakluyt, recording in 1580 "instructions and notes very necessary and needful to be observed," points out that "in the day, your description reckonings, it is the custom to vary a verbal note at the end of every foure glasses what way the shippe hath made (by your best prooves, to be used) and how her way hath beene through the water, considering withall for the sake of the sea, to account, according as ye shal finde it growe. Doe you daily observe the latitude as often, and in as many places as you may possible; and also the variation of the compass..." These instructions, so necessary and needful to be observed, are for air navigation not less so. But in the latter case special difficulties arise. The course over the ground is determined by the apparent motion of objects on the earth relative to the fore-and-aft line of the craft; but owing to the rolling, yawing, and pitching of the latter, and of all instruments carried upon it, such measurements are far from simple. However straight the pilot may try to fly he will yaw slightly from side to side, and this will cause the flight path to be more or less sinuous, and the ground courses to be tending to cause the machine itself, and all instruments fastened to it, to roll periodically to port or starboard. This will cause any effects below the craft to appear as a new and irregular indication of a new flight line, and thus the determination of the angle of drift much more difficult. Nor is it possible to surmount this obstacle by making the observing apparatus pendulous in the hope that it will remain vertical. The lateral acceleration due to the slightly curved path will cause the centre of gravity of the pendulous mass to seek a position such that the moments about the point of support of the weight will balance; in other words, the instrument would tend to swing itself not to the true vertical but to the "apparent vertical" given by the resultant of the gravitational and the lateral acceleration. If the pendulous instrument has a substantial amount of inertia, it will not have time to pick up this direction before the ship rolls, and the pendulous mass will only come to correspond to a fresh position of the apparent vertical. The instrument therefore continually hunts the apparent vertical, but is always in error by an amount of one sort or another. It only appears that by making the inertia sufficiently great the motion of the instrument would be so slow and so slight as to be negligible, but calculation shows that unless gyrostatic forces, with their attendant complication, are employed, it cannot be made to play its part, unless with dimensions of the craft, to achieve this. These ever-present oscillations are of great importance in the study of aircraft instruments. Not only is the apparatus for measuring the angle of drift of the ship required to be fastened by the ship's motion, but the reading of the ground speed, and, by no means least, the magnetic compass itself. Compasses fitted to ships usually have a period of oscillation much longer than that of the ship; and so the apparent compass has not time to be very much disturbed by such movements. In early types of aircraft, however, the period of roll is longer and the easterly of aircraft compass by an unlucky coincidence had just about the same period, hence the period was cut short. The neglected vertical oscillations of the compass needle were all too frequently reported. Later on the cause of the phenomenon was recognized and a remedy was found.

A magnetic compass points magnetic N. instead of true N. gives rise to the correction called "variation," and this applies equally to sea and air craft. Variation charts are equally available and no difficulty. With a free air current due to the magnetism residing in the structure of the craft itself, air currents are simpler than those at sea, in that the masses of magnetic material near the compass position are much reduced; but on the other hand, in the absence of drift, each point of the compass is rather more troublesome to determine and much more likely to vary with the life history of the craft itself.

The measurement of the speed through the air fortunately presents fewer difficulties since these are mostly dependent on relative air stream are dependent only on velocity and air density, and the latter being known for any given altitude of flight it is possible to obtain a measure of velocity through the air free from any correction.

Except for flying-boats engaged on anti-submarine patrol scarcely any aircraft prior to the end of the World War had to employ either of these methods of determination; since these methods of determination were used, the flying-boat, and the flying-boat in the development of the flying-boat, proved possible. The work of the flying-boat patrols, however, required meticulous care in navigation since their duties carried them far out of sight of land and it was imperative that they should make a note of all dead-reckoning carriage carried out with that care which the risk
of failure made necessary for all employed on this arduous service. That so few flying-boats were lost on such patrol's says much for the care with which the instruments were attended to and the skill with which their indications were heeded. An error of only two degrees in the course made good would throw the position by over 3 m. in each 100 flown; the consequences on a misty day for an aircraft trying to make, say, the Scilly Is. base can be imagined. There were then no facilities for astronomical navigation, and dead reckoning had to be relied upon.

Not only had the flying-boats on war service to be navigated but the pilot and observer had also to "navigate" a bomb to its desired target. Since a bomb, or any other heavy body, maintains the course and speed of its carrier aircraft substantially unaltered during its fall to sea level, the sighting problem is the same as the dead-reckoning navigation problem: in fact, one observing instrument can serve both purposes. The horizontal motion of the bomb is compensated by the wind velocity and the air speed of the craft. The distance it will travel horizontally will be the product of the resultant of these two velocities and the time taken to fall from the height at which the aircraft is operating. This then must be the horizontal distance of the craft from its target at the moment of release and the line of attack must of course be that of the course being made good. The angle of the vertical which the target subtends at the moment of release is called the sighting angle, and obviously it will vary with the direction in which the target is attacked unless the wind velocity happens to be zero. This requires that the instrument should be set for height, air speed, wind velocity and wind direction, and further that it should make automatic provision for the right combination of these elements for any direction of attack.

The best known instrument for doing this is the course-setting sight shown in the illustration (fig. 23), and much used on flying-boats; in its navigational use it enables the velocity and direction of the wind to be measured whilst in flight, and it indicates the course to be steered for any given track, the time taken in flying any desired distance in that direction. Towards the end of the war the French made some use of navigational bomb sights, and the United States Government had a large number constructed, but so far as is known no such efforts were made elsewhere.

For D.R. navigation on land aircraft use is often made of an instrument called an aero bearing plate, which was an adaptation of a marine bearing plate, or pelorus, having a transparent centre to admit of vertical observations of the ground, and having one or more longitudinal rods or wires which could be aligned parallel to the apparent earth's flow so as to enable the drift angle to be read off. A great deal more information could be obtained by noting the time taken for an object on the earth to pass through the vertical angle corresponding to a distance of flight of half a mile, or other convenient distance.

Navigational Instruments. One of the first instruments known to have been used for the determination of latitude in maritime navigation was the astrolabe. This device consisted of a pendent disc graduated round its circumference in degrees and carrying at its centre a rod fitted with back and fore sights the inclination of which to the horizontal could be read off on the degree scale. A sight on a star would therefore give a measurement of its altitude, the declination of the disc being known. The altitude of a "plumb bob" is, of course, a familiar way of obtaining a vertical line, but it suffers from the disadvantage that it no longer indicates true if its point of attachment is not kept still. On board ship the point of support is necessarily general and it is not always easy in any position to maintain an unbroken line of sight from the eye to either position (1) or position (2). The former is best for star or planet observations, and the latter for those on the sun, though theoretically there is no reason why either position should not be used for all navigational purposes. When the "plumb bob" is used, a star is more easily identified and held in view by the method of direction of vision, whilst for observations of the sun there is less confusion in using it, as the celestial body is so much bigger, and in any case the position of the observer is not so critical. There are other methods of determination of latitude, such as the use of the barometer to determine the height of the sea, but these are only of use at seaports or when the ship is alongside a land mass.

The principle of action of the R.A.E. instrument is shown in fig. 24. In this instrument—known as the R.A.E. bubble sextant—the vertical is given by the position of the bubble in a spherical vessel. Now, the position of a bubble is being illuminated by light from the observation position is such that it may be taken to be either position (1) or position (2). The former is best for star or planet observations, and the latter for those on the sun, though theoretically there is no reason why either position should not be used for all navigational purposes. When the "plumb bob" is used, a star is more easily identified and held in view by the method of direction of vision, whilst for observations of the sun there is less confusion in using it, as the celestial body is so much bigger, and in any case the position of the observer is not so critical. There are other methods of determination of latitude, such as the use of the barometer to determine the height of the sea, but these are only of use at seaports or when the ship is alongside a land mass.
carefully chosen to be equal also to this distance, the bubble will remain in focus and will appear to move with the sun or star if the instrument’s index mark is in the hand.

Gyrostatic Horizons.—When sextant observations are made at a ground station it is best to employ an artificial horizon, usually in the form of a bath of mercury. The sextant is then used to measure the angle between the heavenly body itself and its image seen in the reflecting surface of the mercury; half this angle is the angle of elevation of the body above the horizon. Such a method is inadequate for aircraft work for two reasons: first, that the bubble would cover the mercury surface with ripple and cause it to reflect a shimmer instead of a definite image; and secondly, that the acceleration forces would act on the mercury and cause its surface to tilt in one direction or another. For this reason use has therefore been made of a little gyrostat spinning on a pivot and carrying a small circular mirror fixed at right angles to the axis of rotation. If this gyrostat accurately keeps its axis vertical the little mirror would form a convenient substitute for the mercury bath. But it also is subject to the disturbing effect of acceleration forces, and is therefore deflected more or less from the desired position. Its behaviour in this respect is, however, much in advance of that of a simple pendulum or bubble; although since it is a rotating body it has the disadvantage of requiring power to drive it, and of being adversely affected in its performance by the inevitable wear of its pivot. It is still uncertain whether a sextant using a bubble or a little gyrostat will in the long run prove the more suitable for air purposes. Gyrostatic means of measurement are, however, of much importance for air navigation, and the first application on a wide scale is that of the gyrostatic “true” horizon in early compasses in which a gyrostat is spun in bearings so that its axis lies normally in a horizontal plane. If then the framework containing the bearings is turned about a vertical axis—due to the aircraft carrying it turning to port or starboard—the gyrostat will tend to itself about an axis perpendicular alike to that about which the forced turn occurs, and that about which the gyrostat itself rotates. This effect is called “precession” and the couple brought into it is called the “precessional couple.” This couple is caused either to compress or to wind up a spring and in so doing to move a pointer, the indications of which give a measure of the degree of rapidity of the turn, and whether the direction is to port or starboard. The use of a gyrostat in aircraft will probably have a bearing on the rate of roll of ships (apparatus for this purpose was made both by J. B. Henderson and H. E. Wiemeris prior to the World War) and its use on aircraft came in the later stages of the war. In the meantime an aircraft turning indicator due to H. Darwin had been employed; this depended on the static air pressure at the two wing tips being communicated to a differential manometer (air-speed indicator type) and a reading being given whenever the aircraft turned, since in so doing it introduced centrifugal forces which in turn affected the static balance of the two pressures and so gave a plus or minus deflection of the manometer needle. The instrument works well, but needs more attention than the gyro device.

Gyrostats are also used in aircraft as azimuth indicators for experimental or test purposes; they may some day be used as part of a gyroscopic compass, but the necessary weight limit will make their introduction for this purpose a matter of some difficulty.

Magnetic Compass.—The design of the magnetic compass as applied to aircraft has in late years undergone a marked improvement. Quite early tests showed that the compass should be a liquid one, and that—to avoid the effects of vibrations—the liquid should be above the cup. But most of the early compasses had periodic times of oscillation about equal to those of the airplanes on which they were carried, and resonance in vibration took place, so that when the airplane rolled even a little, the compasses oscillated widely. Introductions of considerable speed, however, introduced false readings of a turn when flying on any course between N.E. and N.W. The simplest explanation of this phenomenon (first given by Keith Lucas at the Royal Aircraft Factory in 1915) is that since in these latitudes the north-seeking magnetic needle tends to dip downwards it is customary to add a weight to the south end in order to keep the compass card horizontal. When an airplane is in motion the dip of the N. end of the compass card being acted upon by a centrifugal force acting from E. to W. and hence tends to turn the compass card also to starboard. An ideal compass would remain pointing exactly N., and the turn of the aircraft to starboard would be precisely marked by a compass mark from N. towards E. around the compass card; but if the card is also rotating in the same direction, and at perhaps a greater angular speed than the airplane, the lubber mark may appear to move towards the W., giving the false impression of a turn to port. Hence a flier unable to see the ground may infer quite wrongly that he is turning to port when he is really turning to starboard. In order, as he thinks to correct his turn, he tends still more to starboard whereas he really should have turned to port. The compass therefore fails to keep him on a straight course. Many of the earlier types of compass had this defect, but by making the compass period very much longer than the period of rotation by H. E. Wiemeris and by Lucas, it has been made very much greater (as suggested later by Campbell & Bennett), the northerly turning error was either eliminated or greatly reduced.

There is, however, a practical limit to the length of the periodical time of the compass, as this would be too long and the horizon cannot be differentiated from the ordinary navigation: it is too sluggish in giving its indications. This limit also concerns the highly damped—or aperiodic—compass, but in his case the damping is introduced by a weight which is causing the making of the damping approach the aperiodic than in any other way. Theory indicates that the performance of compasses is governed more by the product of undamped periodical time and the damping than by either of these measures. For the early types of compass both elements entering into the product were too low; this was remedied by Keith Lucas in the one direction and by Campbell & Bennett in the other. Actually it is best to use both together to the limit of not making the compass too slow in its movements.

Air Speed and Height Measurements.—The measurements of air speed and height are linked together, since both depend on the temperature, pressure and density of the air. The usual form of air-speed indicator, first made by M. O’Gorman in 1911, makes use of the difference in the air pressure in two tubes, one of which has an open face on the direction of motion, and the other a closed end, but with a hole in the side. In the latter the static pressure is read, and in the former the larger pressure due to the addition to the static of the kinetic effect of the air speed. A simple instance of a similar principle is the Smerling, in which by having the surface facing up-stream it will be wetted higher up than the one facing down-stream. The difference in height is a measure of the difference in pressure. The indication of the later, when the case of a compressible fluid like air it also depends on its density. In fact, the reading of the air-speed indicator is proportional to the product of the density of the air, by the square of the velocity of the air. Since this last quantity cannot be read correctly at sea level, it follows that the “indicated” air speed will always be less than the true air speed at altitude. Thus an aeroplane travelling at 140 m. an hour at a height of, say, 21,000 ft, will on a clear winter day be going on the air-speed indicator—Such indicators are therefore sometimes provided with circular calculators around their circumferences to enable the true air speed to be read for navigational purposes. For aerodynamic purposes such corrections may be quite unnecessary since the forces due to air pressure acting on the wings, the fins, the tail and all other surfaces will also be proportional to the product of air density by the square of the velocity of the air. This is the same as saying that the air-speed reading proportional to this product is, for this purpose, ideal and needs no correction. So that, although for purely navigational requirements it might be thought advisable to introduce a type of air-speed indicator in which the speed is read on an instrument which is proportional to the air density, this does not appear disadvantageous from the purely flying point of view. Hence it is best to retain the present instrument and add to it readings for navigational purposes a circular calculator to effect the conversion. The case of height is the opposite. The instruments provided in the aircraft device if the true height is to be read. Almost all altimeters in use are based on the pre-flight aneroid in which the trade convention of setting the instrument at sea level to 1013 mbar then becoming one division for every 100 m. Although this is not widely out for the average surface temperature it is manifestly most incorrect at a height, since on the average the temperature falls by about 6°C. for every km. (28.2°F. per m.).” The instrument would then read at 1000 m. in the equator and about 21° below the assumed steady level of 10°C.; a difference of about 7%, leading to an over-estimate of height by the same amount. This is corrected by reading the temperature where the aneroid is, and using this as a correction to the height indicated (the A.M.L. height computer)—as in the case of the air-speed indicator—

**Fig. 24.**
to give the true result. For surveying work an accurate measure of the height is of special importance.

Reduction of Altitude by Observations.—The traditional method of
measuring altitude by observation is to employ logarithmic tables for the solution of the spherical triangle. The problem is: given the declination of the heavenly body, the latitude of the assumed position and the hour angle, to determine the altitude of the body. This is done by giving two sides of the spherical triangle and one of the angles, or vice versa; the other angle and one side determine the triangle.

To make this calculation by means of logarithmic tables is simple enough on board an airship, but is not easily performed in an aero-
nor is the degree of accuracy possible without the existing equipment.

To avoid these difficulties, a method was suggested by VECTOR of employing a Mercator projection of the sphere and using various curves drawn thereon to solve the spherical triangle by the equivalent of a rotation of the sphere. This method is more accurate than the older methods, and is not required; but it was difficult to use the curves without eye strain, and the method eventually gave place to the cylindrical slide rule devised by L. C. Bygrave. The whole procedure is by this means made both easier and more accurate and reliable, and the practical result is a

much more satisfactory method, which also offers the advantage of being capable of use for the determination of the position of both sea-
craft and aircraft. The invention followed from the discovery of a method by which the direction from which wireless waves were arriving can be found by an analogy with the determination of a

bearings, was it possible to determine, from the receipt of ripples at the margin of a pond, the direction of the spot at which a stone had fallen into the water. It was found that if a rectangular coil hap-
pened to be placed from which the wireless waves were travelling, no current would flow in the coil, whilst if the latter were placed "edge on," it was possible to detect an oscillating current in the coil. In intermediate positions, intermediate results were obtained. Once, therefore, a search coil of this kind is mounted on a vertical axis it can be turned until the current is either a maxi-
mum or a minimum, and by these means the direction of the sending
station can be determined. It is true that a station N.E., say, could not be

distinguished from one to the S.W., but other considerations usually enable a right choice to be made from these two alternatives.

In practice various electrical improvements have been made on this simplification. The principle is the same, and it is obtained by such means which are of importance to the navigator.

The navigator will of course require of the wireless officer that W/T bearings so given shall be "true," and that corrections due to any possible errors in their determination shall have been allowed for.

There are two methods by which "directional wireless" (as it is
termed) may be employed. The first and simplest is by having suit-
able search coils mounted on a wire under ship. The second method is the use of such beacons take note of the direction of the calling aircraft, and communicate with each other so that one of them can plot on a map the several bearings which, by their common point of intersection, determine the position. This is then transmitted to the aircraft. This plan has the double disadvantage that the aircraft is forced to disclose its position, and that the number of messages sent out "into the air" is thereby increased. The alternative is to mount the search coil in the sending craft and for the latter to determine the bear-
ings of two or more sending stations, and to do its own position-
plotting on the chart. The latter alternative is usually preferred, but it suffers from the difficulty that it is impossible to obtain immediately prior to receipt by the influence of the many flying, and other, wires forming part of the structure of the aircraft. These are called quadrantal errors, and they correspond to the horizontal parallax of a simultaneously observed compari-

tion were not allowed for. A difficulty common to both methods lies in the bending of the ray's direction when crossing a coast line, or the boundary of day and night—such effects need to be allowed for. The problem is solved by employing more-wires, or by using a combination of the above methods. But if, as is usual, a Mercator chart is employed, it has to be borne in mind that straight lines on such charts are not great circles, and since the waves travel along the latter (except at the equator) it is better to draw the path of the waves by means of a certain curve, the bending of which will depend on its distance from the equator. Approximate methods of doing this are necessary, and the best method (following Vosper) is to make use of the Littrow projection of the sphere (more familiarly known as the "Weir diagram").

Much work has still to be done before it can be determined how accurately the position of an aircraft can be found by means of
directional wireless. But there is a great advantage in position find-
ing, since it enables a straying aircraft to fly back to its parent ship by flying "home" along the wave path. Its path may not be a straight line, and it may take some time to make the flight, but if persisted in it is bound to bring the aircraft home sooner or later.

World Flights.—The famous world flights of 1919 and 1920 were
the transatlantic crossings by the American flying-boat NC4, by the Vickers-Vimy aeroplane, and the rigid airship R34 (not forgetting the gallant attempt of the Sopwith aeroplane); the flight to Australia by a Vickers-Vimy aeroplane, and the several attempts to fly an aeroplane down the length of Africa.

In the case of the Australia flight the coast line was usually
followed and methods of air pilotage, as distinct from air naviga-
tion, sufficed. The African flights were in part over uncharted
territory, and pilotage alone did not suffice; both there and, of

course, in the transatlantic flights the course was slower

by navigational methods. In the case of the R34 the operations
were carried out by officers accustomed to the navigation of
naval ships, and in so rosy a craft the work was much more
easily arranged than in the more compact aeroplanes and flying-
boats. Comm. Mackenzie Grieve, the navigator of the Sopwith,
asserted that even in his tiny aeroplane he navigated by celestial
observations and found that his position, as given by his ob-

servations of the stars, when picked up after the forced landing
in the sea was "practically correct."

The instruments available in 1912 for navigation were much more
rudimentary than those in use prior to 1920. In future world
flights the determination of position, course and speed will not
only be simpler and more speedy, but will also be very much
more accurate than anything hitherto known in the history of
air navigation.

VII. CONTROL OF AIR TRAFFIC

The pre-war legislation of individual States generally pre-
sumed sovereignty of the air, but the doctrine was not finally
accepted until the World War. Thus in 1911, at the Madrid
session of the Institute of International Law, a resolution was
passed that "International aerial circulation is free, subject
to the right of States to take certain steps, which shall be
fixed, to ensure their security and that of the persons and property
of their inhabitants." This principle was modified in the Report
of the Committee on Aviation of the International Law
Association in 1913—

"It appears to the Committee impossible to contend that accord-
ing to the existing International Law, States more than others
that States would be willing to accept or to act on that view of
the law. But they are of the opinion that, subject to such safe-
guards as subjacent States may think it right to impose, aerial
navigation should be permitted as a matter of comity."

Though in some quarters the assertion of state sovereignty
only up to some prescribed height was advocated, individual
States, and among them Great Britain, asserted, mainly for
military reasons, their right to close their atmosphere abso-
lutely (nusque ad coelum) to the aircraft of other States. It was
the conflict of opinion between the British and German delegates,
as to the right of each State to the exercise of control and juris-
diction in the air space over its territories, that prevented the
completion of an International Convention by the conference
held in Paris in 1910. By the first British Aerial Navigation
Act (1911) power was taken to prohibit the navigation of air-
planes over prescribed areas. In the Act of 1913 this power was
extended for the purposes of the defence or safety of the realm
to the whole or any part of the coastline of the United Kingdom
and territorial waters, while the Statutory Rules and Orders of
that year limited the landing areas for aircraft coming from any
place outside the United Kingdom to a comparatively few strips
of coastline, and forbade foreign naval or military aircraft to
pass over or land within any part of the United Kingdom except
AERONAUTICS

with express permission. By a French decree of 1913 the circu-
lation in France of foreign military aircraft was forbidden, and
the draft Franco-German Agreement of 1913 practically
admitted the principle of the sovereignty of the air by allowing
each country the right of making such regulations as it pleased
for flights above its own territory.

For the beginning, therefore, air sovereignty and air legis-
lation were influenced by a predominantly military conception
of aviation, and, on the outbreak of war, the doctrine of the
freedom of the air was doomed. In the words of the Civil Aerial
Transport Committee in 1918: "Since the outbreak of the war
sovereignty over the air has been generally claimed and, except
by Germany, recognized." During the war neutral countries
consistently regarded the passage of belligerent aircraft over
their territory as an unequal act.

Pre-war legislation was in spirit and effect distinctly national,
and in Great Britain regulations affecting the entry of foreign
aircraft from abroad were stringent. In the case of airships a clearance from a
British consular officer was required, and in the case of aeroplanes notice
had to be sent to the Home Office giving the proposed place of
landing, time of arrival, and nationality. Aircraft were forbidden to
carry mails or goods chargeable upon importation, and before
departure were obliged to report to an officer at one of the pre-
scribed landing places. Moreover, the registration, certification,
and marking of the navigation of aeroplanes within four m. of Charing
Cross and of a number of small areas over which flying was prohibited
on military grounds, there was no State regulation of flying, and
certificates of licences and identity were issued by the Royal
Aero Club, which represents Britain on the Fédération Aéronautique
Internationale.

A similar state of things existed in France until the passing of the
Aerial Navigations Act of 1913, which was to a considerable extent
based on the draft Convention of 1910, and made the owner of an
aircraft responsible for damage to property, provided for the regis-
tration, marking and inspection of aircraft, pilots' certificates and
licences, the admission of aerial navigation over the territory
of foreign States, customs and transportation, and rules of the
air. The international aspect of aviation did not, however,
completely die with the failure of the Convention to materialize.
The Institute of International Law, in its session of 1911, adopted
rules distinguishing aircraft as public and private, confining an
aircraft to one nationality, i.e. that of the country in which it
was registered, and imposing identification marks. Another
step in international air traffic was the Franco-German Agree-
ment of 1913 permitting the entry of civil aircraft into each
country subject to the conditions that machines were provided
with navigation licences and distinctive identification marks,
that the fliers were provided with proficiency and nationality
certificates, and that the requirements of international law
and the customs and air regulations of each country were
observed.

In England in 1913 the Convention of 1910 was reconsidered
by a sub-committee of the Committee of Imperial Defence; and
when the advance in flying during the war indicated the great
potentials of aircraft for civil transport, a Civil Aerial Trans-
port Committee under the chairmanship of Lord Northcliffe
was appointed by the Air Board in 1917 to consider the whole
subject, both from its international and national aspects.
It was not, however, until after the Armistice that the first steps
were taken by a departmental committee of the Air Ministry
to frame regulations for civil flying in Great Britain. Shortly
after, the drafting of a Convention governing international civil
flying was included in the work of the Peace Delegates at Paris—
the coordination of the British proposals therewith being under-
taken by Sir Frederick Sykes, and took shape as the Interna-
tional Air Convention, which was signed by the majority of the
Allied and Associated Powers on Oct. 13 1919, though up to
Aug. 1921 ratification was not yet complete.

The objects aimed at by the Convention are the encourage-
ment of the peaceful intercourse of nations by means of air inter-
communication, and the establishment of a broad basis upon
which a uniform procedure for the control of air traffic can be
drawn up by the contracting States.

The drafters of the Convention recognize the exclusive
sovereignty of every Power over the air space above its own territory
and territorial waters and those of its colonies, and while each contracting
State allows freedom of innocent passage above its territory,
the States are free to determine for certain reasons, to the air-
craft of other contracting States, it may not, except by a special
temporary authorization, permit the flight above its territory
of aircraft belonging to non-contracting States. Article 2 of draft of
the Convention, however, allows the right of the aircraft owner,
with the consent of the State then in control of the area
of the air space in question, to cross the air
space of another State without landing, subject to following the route
fixed by the State, but if it passes from one State into another it must
land, if required to do so by the regulations, at an appointed aerodrome.
Every State has the right to establish reservations and
restrictions in favour of its national aircraft in connection with
the carriage of persons and goods for hire between two points in its
territory but is liable to reciprocity on the part of other States. Any
aerodrome in a contracting State open, on payment of charges, to
public use by its national aircraft, is likewise open to the aircraft
of all the other contracting States.

Aircraft engaged in international navigation must be provided
by the State whose nationality it possesses with certificates of registra-
tion and airworthiness, certificates of competence and licences
for the crew, which must be valid for a period not exceeding the
duration of the flight of an aircraft over the areas in which the
aircraft is to fly, and, if with freight, in bags of lading, log books and
a special licence for any wireless equipment carried.

The Convention forbids the carriage by aircraft, engaged in inter-
national service, on the territory of another State, of goods,
private, i.e. aircraft which are not used for military pur-
poses, or employed exclusively in State service, subject to the
provisions of the Convention.

Annex A to the Convention give detailed regulations with regard to the marking of aircraft (Annex A), certificates of air-
worthiness (Annex B), log books (Annex C), lights and signals of the air (Annex D), pilots' and navigators' licences (Annex E),
maps and ground markings (Annex F), the collection and disseminaton of meteorological information (Annex G) and
customs (Annex H).

The Convention provides for the establishment of a permanent
International Commission of Air Navigation, affiliated to the League
of Nations, consisting of two representatives of the United States,
France, Italy, and Japan, one representative of Great Britain and
France, Italy, and Japan, one representative of Germany and
Austria, and one of each of the other contracting States, for carrying out the terms of the Convention and the
interchange of information.

A permanent and special committee to the interpretation of the
Convention and technical regulations are to be settled respectively
by the Permanent Court of International Justice and a majority of
the States signatory to the Convention, or their representatives
at Paris 1914-9 but which is not a signatory of the Convention may
directly to adhere to it if a member of the League of Nations, or, until Jan. 1
1923, if its adhesion is approved by the Allied and Associated
Powers. After that date if it is agreed to by at least three-fourths of
the signatory States.

States which remained neutral during the war have availed
themselves of the Article permitting their adhesion to the Conven-
tion, mainly owing to the restriction placed by Article 3 on the
intercourse by air with late enemy States. To overcome this
difficulty, a Protocol was subsequently added to the Convention
permitting certain derogations to Article 3 and authorizing the
contracting States profiting thereby to allow, for a limited period
of time, the aircraft of one or more named non-contracting States to
fly over its territory.

The above Convention of 1919, the charter of international
flying, may be regarded as prescribing the minimum control
required from contracting States. There is no reason why States
should not make their regulations more stringent for
the benefit of the interest of safety and efficiency. The harmoniza-
tion of the regulations enforced by the contracting States will
undoubtedly form an important part of the functions of the Inter-
national Commission of Air Navigation.

During 1919-20 a large number of countries, including, among
others, Great Britain, France, Belgium, Spain, the Scandinavian
kingdoms, Holland, Italy, Switzerland and the new Mexico, were
influenced in their modifications in the original regulations, have been
favourably, or unilaterally, to 1920-21. Thus the British
Aerial Navigation Act of 1919, and the Regulations
issued by its authority which were influenced by, but actually
preceded, the signature of the Convention were only temporary, and
were superseded by the Air Navigation Act of 1920.
The Act of 1920 asserts absolute sovereignty over all parts of His Majesty’s dominions and adjacent waters, provides for the application of the Convention by Order in Council to internal flying, the regulation of civil flying and the supplementing of the Convention, as necessary, by general safety regulations. It authorizes any steps to be taken for preventing aircraft from flying over prohibited areas or entering the British Islands in violation of the law, and permits the extension of the provisions of the Act to British Possessions other than the Dominions and India. The Act also provides for the prohibition of all flying, and the taking over of aircraft, etc., in time of emergency, the surrender and disposal of aircraft and the Air Council or local authorities; purchase of land; compulsory investigation of accidents; and penalties for dangerous flying. No action having regard to treason or reason of peace, the aircraft over any property at a reasonable height above the ground, or the ordinary incidents of such flight, so long as the provisions of the Act and Orders made thereunder are complied with, but the law relating to wreck and salvage at sea applies to aircraft in the same way as to vessels.

Administration.—The methods of administration adopted in Great Britain in conformity with the Air Navigation Acts were probably, in 1921, in advance of those in other countries, but they might be regarded as typical of what would be required, at least for a time, in other countries. The Royal Aero Club certificate is accepted as a certificate of competency, the Club having agreed to bring their tests for this certificate into line with those laid down in the International Air Convention. A certificate of the Royal Aero Club in England; the Royal Aero Club must issue a private pilot’s licence for a licence to fly a passenger or goods aircraft for hire or reward an applicant must undergo a medical examination, pass certain practical flying tests and a technical examination, submit proof of reasonable flying experience within the previous six months on the class of machine for which a licence is required, and pass an examination in navigation and elementary meteorology. In the case of applicants who are qualified as R.A.F. pilots the tests are limited to an examination in navigation and meteorology. Licences are issued for six months. There are five grades of licences for navigators. Aerial navigators, fourth-class, are licensed only to navigate civil aircraft over land by day, those qualified for the third-class certificate are licensed to navigate only over land by day or night, whilst those attaining the higher classes are licensed to navigate over both land and sea by day or night. Licences for ground engineers, usually valid for twelve months, may be obtained for the inspection and maintenance or overhaul of aircraft or engines.

(i) Registration of Aircraft.—Every aircraft must possess a certificate of registration, which lapses on change of ownership.

(ii) Licensing.—For a private pilot’s licence the Royal Aero Club certificate is accepted as a certificate of competency, the Club having agreed to bring their tests for this certificate into line with those laid down in the International Air Convention. A person qualified as an R.A.F. pilot is entitled to a private pilot’s licence. For a licence to fly a passenger or goods aircraft for hire or reward an applicant must undergo a medical examination, pass certain practical flying tests and a technical examination, submit proof of reasonable flying experience within the previous six months on the class of machine for which a licence is required, and pass an examination in navigation and elementary meteorology. In the case of applicants who are qualified as R.A.F. pilots the tests are limited to an examination in navigation and meteorology. Licences are issued for six months. There are five grades of licences for navigators. Aerial navigators, fourth-class, are licensed only to navigate civil aircraft over land by day, those qualified for the third-class certificate are licensed to navigate only over land by day or night, whilst those attaining the higher classes are licensed to navigate over both land and sea by day or night. Licences for ground engineers, usually valid for twelve months, may be obtained for the inspection and maintenance or overhaul of aircraft or engines.

(iii) Airworthiness.—In order that an aircraft may receive a certificate of airworthiness, its design, including the design of its component parts, its materials, the strength and safety in regard to both strength and stability; it must be constructed of approved materials and by workmanship of approved quality, and its engine must be approved. In order that such a certificate may be valid on any particular occasion the aircraft must be examined before flight and be periodically overhauled by a competent person duly licensed; it must be so loaded that its total weight does not exceed a given maximum, and its centre of gravity must be situated within certain given limits. If the application for a certificate is in respect of a “type” aircraft, inspection is carried out by representatives of the Aeronautical Inspection Directorate, and, in addition, such drawings and particulars are required to be furnished to the Director of Research, as will enable him to approve the design. In the case of subsequent aircraft constructed by a firm where inspection is approved by one representative with the Aeronautical Inspection Directorate, the constructor ensuring that the conditions governing the inspection of “type” aircraft are applied to subsequent aircraft. A certificate of airworthiness is not valid unless the aircraft concerned is regularly inspected by a licensed ground engineer employed by the owner of the machine.

(iv) Aerodrome Licences.—The regulations for aerodrome licences are prescribed by the Air Ministry, and only those aerodromes which are safe for passenger work receive licences.

The dimensions laid down as a preliminary guide for the classification of aerodromes are as follows:

- 800 yd., run in the direction of the proposed run, with good approaches, etc. Suitable for any type of aircraft.
- 600 yd. Suitable for all but the larger types of aircraft, i.e. not suitable for large machines.
- 300 yd. by 400 yd. Suitable as permanent aerodrome for aircraft of Avro 504K or similar types.
- 300 yd. run in any direction. Temporary aerodrome for Avro 504K and similar types.

Any aircraft may use a licensed aerodrome of the appropriate class, subject to the payment of the landing and housing fees approved at the time of the issue of the licence.

Ground Organization

(i) Air Ports. (a) Aerodromes.—The early aerodromes were usually any large, level grass fields, and the first real aerodromes were established in France, England, Germany and America. Their early equipment consisted only of rough sheds for aeroplanes, and ills carried out at the local smithy or garage such repairs as could not be done on the spot or in their own homes. Repair shops were only available at a very few of the military flying grounds. As aerodromes became more numerous, workshops equipped with power-driven machinery were established at large aerodromes such as Farnborough and Hendon, and the occupations of "aeroplane mechanic" and "aeroplane rigger" were defined. With the increase of flying, certain rules were laid down for the control of aerodromes; aerodromes were not allowed to be moved about the aerodrome without ascertaining that they were clear of other craft alighting, and when in the air in the vicinity of aerodromes, were obliged to conform to circuit rules, i.e. machines were made to circle round an aerodrome in a direction, which with a coloured flag hoisted in a prominent position; and some form of indicator, such as a smudge fire, was used to afford pilots a guide to the direction of the surface wind.

From these simple rules, the complex system of aerodrome control which developed during the World War was built up. While the original principles of aerodrome management remained the same as in 1914, new inventions produced much greater efficiency. With the advent of night flying new methods of visual signalling were adopted (see below); the bucket flashes, used at the beginning of the war to indicate wind direction, were replaced by electric lights or the "Money" flare; and a standardized system was introduced to mark the positions of aerodromes and arriving at an aerodrome in quick succession both by day and night.

The results of the experience accumulated during the war in the control of aerodromes were embodied after the war in Annex D of the International Air Convention. According to the regulations laid down therein, every aerodrome consists of three zones looking up-wind: a right-hand or taking-off zone, a left-hand or landing zone and a neutral zone. At night the taking-off and landing zones are marked by white lights placed in the position of an "L," as shown in fig. 25.

![Fig. 25](image-url)
AERONAUTICS

tress are given free way in attempting to land. At night suitable
markings are required on all fixed obstacles dangerous to flying
within a zone of 500 metres of an aerodrome.

The London terminal aerodrome at Croydon, Surr., may be
taken as typical of a modern air-port for commercial traffic.
It consists of a level grass field 500 yd. long by 800 yd. wide,
and is equipped with a continental arrival and departure station,
a customs office, repair shops and stores, aeroplane hangars
and the private offices of companies engaged in air and road
transport. An indicator, consisting of a conical linen bag, painted
in conspicuous colours and attached to a mast, shows the direc-
tion of the wind by day; and the movements of machines are
directed from a control tower. Along the south side of the
aerodrome the name Croydon is let into the turf in chalk letters
of 30 ft., legible from a height of 10,000 feet. For the assistance
of night flying an aerial lighthouse shows the position of the
aerodrome, while a searchlight distinguishes the aerodrome from
its surroundings and illuminates the path of the machines.
Electric lights are sunk into the ground to indicate the direc-
tion of the wind for landing. A wireless transmitting and receiving
station is installed capable of telegraphic communication with
ground stations within 400 miles and aircraft within 200 miles,
and of telephonic communication within 200 and 100 miles
respectively.

(b) Coastal Stations.—A sheltered stretch of water, usually an
inland lake, was selected by the pioneers of hydro-aviation, a
slipping beach, a rough shed and one or two small boats being
the only other requirements. The equipment of the English
station at Lake Windermere, the scene in 1911 of the first take-
off and landing on water by a British aeroplane, was almost
negligible. In 1911 the first organized seaplane stations came into existence. The management of these stations is very similar to that of an aerodrome, with the excep-
tion of slipways up and down which aircraft are moved on leav-
ing and entering the water, mechanical power for hauling heavy
machines, and wheeled trucks to move them about on shore.
At most of the early stations, however, man-power was sufficient
to move machines, which were small and light, up and down the
slipping beaches, while the pilot was carried to and fro from the sea-
plane while it was still afloat.

The first British flying-boat was produced in 1912, but it was not
until 1913 that larger boats were sufficiently developed to enable
them to stay out on the water for days at a time. This develop-
ment caused a corresponding expansion in the organization of seaplane bases. Launches and rowing-boats,
used previously to assist machines in difficulties, became ferry-
boats for taking fuel, stores, and personnel to and from the
large flying-boats which were moored out to buoys in sheltered
waters adjacent to the coastal stations. The organization and
management of these depots, until the formation of the Royal
Air Force in 1918, was modelled on that of H.M. ships.

Calshot, Hants, was in 1921 the most up-to-date coastal station
in Great Britain; the sheltered area of Southampton Water provides
ample sea room for craft getting off and alighting, while the narrow
promontory on which Calshot Castle stands, almost surrounded by
water, affords an admirable base for the handling of ships in
and out of the sea at most states of the tide. Repair shops, sheds
and landing-quarters occupy a large area afloat: boat seaplanes,
which are gradually replacing float seaplanes for all but special
purposes, are moored out in a backwater; launches and rowing-boats
are moored alongside a small pier, and trucks of special construction
are held in readiness on the beach to move craft about on, when
they have been hauled up the slipways by electric power capstans.

(c) River Stations.—The value of river stations lies in the fact
that they can be located in the centre of many large cities,
and passengers by air can thus save the time, now lost, in reaching
aerodromes necessarily situated on the outskirts. River stations
were still in 1921 in an experimental stage, but stations on the
Thames, the Seine and the Spree will probably be developed to
serve the three capitals—London, Paris and Berlin—which are
already important airline termini.

(d) Airship Harbours.—In the early days of airships any
convenient open space, such as a parade ground or moorland,
was utilized, but as the size increased stations were selected
so as to afford shelter from the wind, accessibility by air and
road, suitable accommodation for personnel, and privacy. In
1907 the Royal Airship Factory, at Rotherthorough, was used for the first airship flights in England, and in 1912-3 it was provided with an elementary
mooring mast. This station was abandoned in 1915. After the
outbreak of the World War large airship harbours and construc-
tion stations were erected in many parts of the United Kingdom,
thus following on the far greater development in Germany.

The first sheds for the housing of airships were comparatively
small and constructed of various materials, such as canvas, wood
or corrugated iron. As the development of the airship progressed
these were superseded by sheds about 750 ft. long, built of corre-
gated iron on iron girders, and capable of accommodating
one large airship and several smaller non-rigid types. The
annexes of the sheds contained all the essentials for the
engineering, carpenter and fabric work as well as stores for
general equipment and laboratories for research.

The development of the airship, however, was so rapid that
it was not possible to keep pace with the construction of airship
stations, which entailed considerable labour and expense.
For this reason other schemes for housing had to be devised.
The first method for small airships was a reversion to the early one
of a house' them under natural shelter, but it had the
disadvantage that the airship fabric rapidly deteriorated by con-
stant exposure.

Owing, however, to the length of rigid airships it was im-
possible to dock them in this manner. Experiments were accord-
ingly made for mooring them in the open by the three-wire system
(see Airships, Section 9). This was superseded by rever-
sion to the mooring mast, which proved so successful that a
large mast was erected at Pulham, where the first attempt
was made in England to organize an airship harbour for com-
mercial traffic, and the largest airships have been moored to it
for long periods and in high winds. The adoption of the mooring
mast has enabled the sheds to be mainly used for the housing
of airships after the latter have been hauled in, repaired, and has
reduced the personnel required for handling airships on the ground
from an average of about 200-350 to an average of eight men.

Airship harbours have facilities for gassing airships with
hydrogen, either from steel bottles or by manufacture on the
spot by the water-gas process.
national code flag signal of distress, a square flag having either above it or below a ball; a continuous sounding with any sound apparatus. When the telegraph key is pressed, the whole key is used to require an aircraft to land; by day, three discharges, at intervals of 10 seconds, of a projectile showing on bursting black or yellow smoke, or a discharge from a single or double red star or lights. In fog and bad visibility, sound signals may be used.

From the date of the formation of the British Royal Flying Corps in May 1912 the importance of wireless telegraphy in connection with aircraft operations grew steadily greater, and at a very early period of the World War its superiority over other methods of signalling from the air was clearly demonstrated. Standard patterns of instrument for naval and military work were gradually evolved; how reliable even these instruments are, may be seen from the fact that a few of them are actually still in use to-day in a practically identical form. The demand for the control of aircraft has increased to such an extent that the British Islands alone are now served by over 600 aeroplanes and approximately 1,000 ground stations in use. All these machines were employing a spark system, and with the advantage of the long-distance reconnaissance and bombing squadrons with their higher-powered sets the need became apparent for improvements allowing of less interference and, if possible, a larger number of machines working within the same limits of wave length.

The introduction in the early part of 1912 of the oscillation-valve continuous-wave transmitter—an extremely light and efficient instrument with a range of 100 m. from air to ground—opened up a new vista with possibilities. Reception of ground-station signals by aircraft, although actually accomplished by the military wing at Farnborough as far back as 1913, became a reliably consistent proposition. Air- craft, equipped with readily portable wireless appliances, were enabled to maintain a constant communication with their base, and, what was perhaps more important, the introduction of the continuous-wave set opened up the possibilities of the design of an efficient points-to-points wireless telephony capable of withstanding the most rigorous usage.

Although hostilities terminated before the full benefits of these latter developments could become effective, the progress which has since ensued, both in service and civil aviation, is considerable. Airways have rapidly sprung into being, and the necessity for rapid signalling along the route, reporting arrivals, departures and delays, and the spread of the community in the air, as in every other sphere of activity, has been responsible for the growth in England of the seven ground stations now existing, and, abroad, of the stations of the continental airports. The Air convention provides that every air- craft used in public transport, sea and air, containing ten persons shall be equipped with sending and receiving wireless apparatus, and to-day most of the passenger-carrying aeroplanes of the London-Paris and other continental routes are equipped for the transmission and reception of wireless telephony and are thus enabled to keep in touch with the ground throughout their flight. On several occasions during the year 1921 telephone conversation has been successfully carried out between a passenger returning from Paris and the Continent and a friend in his own home or office in London; the line telephone being used as far as the aerodrome station at Croydon, and thence being relayed by wireless telephone to the home.

Another important war development, now becoming more and more extensively used, which was the outcome of the determination of the direction of passage of electro-magnetic waves, is the system of wireless meteorological stations, the network of which this system two or more ground stations can detect the position of an aircraft using wireless telegraphy or telephony, and can pass that information direct to it within a few seconds.

The converse—an aircraft taking the bearing by W/T of two or more W/T stations on the ground can plot her own position, and thus enable the navigator to settle his position without asking for any information from the ground stations. This method is still in its infancy, but will undoubtedly prove of value to aerial navigation.

(iii) Weather Information.—The value of the collection and distribution of meteorological information for the assistance of aeronautics was early recognized, notably in Germany. In England in 1909 the Meteorological Office was represented on the Advisory Committee for Aeronautics; in 1910 a meteorological station was started at the Royal Aircraft Factory, and in 1912 at the Central Flying School at Upavon; both of these were equipped with wireless telegraphy and the pre-cursors of the present local distributive stations. During the war meteorological services developed under the War Office and the Admiralty, a portion of the service under the Admiralty being transferred in 1918 to the Air Ministry. In 1919-20 all branches of the Meteorological Service were coordinated and attached to the Air Ministry.

The information required for air traffic day-to-day consists of existing weather conditions on any route, or landing-ground forecasts and warnings. General information as to weather conditions is provided by the Daily Weather Service of the Meteorological Office, which receives information by continuous wave, telegraph, telephone four times daily from a network of observing-stations throughout the British Isles. The reports obtained from these are issued collectively in the form of synoptic maps, the cartoon of which are available to anyone within wireless range either in the British Isles or European countries, while the latter distribute, their local information in a similar manner. According to the code drawn up by the International Commission for Weather Telephony for the information transmitted to the Central Office in these reports consists of surface conditions, atmospheric pressure, wind, general state of the weather, temperature, humidity, cloud, rainfall, upper-air conditions, etc., the observations being provided by each station and relayed to the Central Office. In addition to the above, reports and forecasts usually covering a period of 24 hours are issued four times daily to each of four Aviation Weather Groups into which the world is divided. Warnings are issued from the Central Office to all flying-centres when danger threatens.

Local distributive centres are fully equipped meteorological stations established at certain important flying-centres, especially near airfields and will eventually number about twenty. Their duties include local observation and the issue of special information to the Aviation Services within their area. The establishment of a regular air service such as that between London and Paris entails a distributive station at each terminal, a subsidiary observatory and a relay-route, and the hourly distribution of information. While in the air the flyer can obtain information as to the weather in front of him by wireless telephony or from ground signals. (V. B.J.)

VIII. SEAPLANES

Early Attempts at Flying from the Water.—Among the earliest aircraft designed to fly from, and alight on, the water were a French craft by M. Fabre (1910), the Parseval monoplane constructed in Germany in 1911, and the Grabardini monoplane of 1912, all of which took to the air on the surface of the Adriatic. These planes demonstrated that sea surfaces were a useful launching-grounds, and that the surface was a useful floating-place for aircraft. The first prototype of an Avro seaplane was the Avro 12 with 35-HP. Green engine at Barrow in 1911.

Henri Fabre's "Canard," an original "pusher" monoplane with a 50-HP. Gnome engine, made several straight flights at Monaco in April 1912, and Voisin, Caudron and K. E. Pelterie thereafter successfully equipped their standard aeroplanes with Fabre floats. This float was a fair-sailed, rectilinear in plan, and made of a wooden framework covered with proofed canvas. This type was displaced later by pontoon-shaped floats covered with 3-ply wood or mahogany planking.

In 1912 Collie, on a Voisin "Canard" equipped as an "amphibian" with both wheels and floats, left the land at Issy-le-Moulineaux, and alighted on the Seine at Auteuil. Donnet and Levêque in France in 1912 built and flew the first boat seaplane, a two-seat pusher having a central hull with the engine above the hull, sufficiently high under the plane for the air screws to clear the hull. The tips of the lower plane carried small floats to balance the craft on the water, and wheels were later fitted to the hull. The high centre of thrust relative to its centre of gravity, which signalized this craft, had been demonstrated in 1909 by Blériot on an aeroplane. The design of this boat generally made it the forerunner of the seaplane of 1921. In 1912 the Royal Aircraft Factory equipped eight F.E. biplane pusher floats, and later a tractor biplane was made there and flown from Frensham Lake to Southampton Water.

In the first half of 1913, Poteaupré's L1 and L2 with 100-HP. Gnome tractor biplane waterborne on a single central float and small wing tips floats. On the next seaplane, however, two floats were used in place of the central float. These craft and their successors proved fairly seaworthy, and were useful on naval manoeuvres. About this time the experience of the shocks met with, when flying from broken water, led to the use of rubber shock absorbers, between the floats and the supporting struts.

In America, following the lead of Glenn Curtiss, several aeroplanes were fitted with pontoons. Towards the end of 1912 Curtiss replaced the single central pontoon by a boat-shaped
hull, which carried the tail members. To protect the crew, a wood and canvas superstructure had been built on the fore-part of the original pontoon, making its appearance very similar to that of the later Curtiss flying-boats. With experience this pontoon was extended further aft to carry the tail members, and so this flying-boat appears to have been progressively evolved.

In April 1913 a prize of £10,000 was offered by the Daily Mail for crossing the Atlantic in 72 hours, and Rodman Wanamaker had a 1,000-h.p. Curtiss flying-boat, called the "America," made for this. Loaded to the necessary 5,000 lb. gross, it could not leave the water. With a third engine it could do so, but the air endurance was thus reduced, and in July 1914 the flight was abandoned.

**War Period.**—Up to July 1914 seaplane design was thus very backward, and its war usefulness to a fleet was but little indicated. The non-existence of any particular line of advance that could be systematically developed had adversely influenced its evolution. In England in 1914 seaplanes were used in coast-defence work, and one seaplane carrier was in commission. By Aug. the carrying of aircraft on board ship had been facilitated by the introduction of folding wings, and their offensive value enhanced by the successful launching of a locomotive torpedo from the air. This led to the conversion of small passenger vessels into seaplane carriers, and soon the merits and limitations of the float type of seaplane were ascertained. As no launching- or landing-deck was available, the seaplane had to be operated from the sea, and this could be undertaken only in very favourable weather. An increase of air endurance and useful load was achieved, but at the expense of some of the seaworthy qualities. With a crew of two, wireless, and about 60 lb. of bombs, an endurance of two to three hours at 70 knots was possible.

By 1915 an improvement of the same type (known as the "Short 184"), which survived throughout the war, could carry a heavier load for about five hours. They were intended mainly for duties with carrying ships, originally proposed for service with the fleet, and with the light cruiser and destroyer squadrons. As, however, these "float seaplanes" lacked sea-going qualities, and their carrier ships were vulnerable, many of the operations intended for them were abandoned. They were utilized in the Gallipoli campaign.

Air-cooled rotary engines, used on the seaplanes of 1914 because they gave the lightest weight for power where weight was a cardinal consideration, soon proved unsuitable at sea, and were replaced by water-cooled engines. "Float seaplanes" were also employed with the Grand Fleet during the first two years of the war for observation with the fleet at sea, and patrol, but they were handicapped because their sea-going qualities were not adequate for the bad weather prevalent in the North Sea. At this time only one ship was provided with a forecastle deck large enough to enable a seaplane to be launched therefrom on a light subsidiary carriage, thus avoiding the necessity for stopping the ship with the attendant risk from submarines, when getting a seaplane into the air.

In the absence of seaplanes with good sea-going qualities, ordinary aeroplanes were carried in fighting-ships with a launching-platform. Latterly carrier ships have been evolved with an alighting-deck as well. This led to the small seaplane not being pressed forward in the way the small aeroplane was by the stimulus of the war.

**The "Boat Seaplane."**—In 1914 there was in the British service a small Sopwith boat seaplane fitted with wheels (winner of the Mortimer Singer trophy), and also two small French and American machines. They could not carry any appreciable load nor could they be launched or folded from carrier ships; accordingly they were not then developed. In July 1914 Lieut. Porte, who was engaged upon the twin-engined boat seaplane, the "America," previously mentioned, was instrumental in developing the modern "boat seaplane." In 1915 several "Americas" with their two 90-h.p. engines were delivered at Felixstowe. Their performance was poor on account of their lack of horse-power for their weight; and they were too small—36 ft. hull—to give good sea-going qualities.

The much larger "Porte" boats with their three engines of 275 H.P. and air endurance of 8 hours, a total weight of about 8 tons, and a hull 60 ft. long, were laid down. The increase of dimensions carried with it a great improvement in sea-going qualities, but the air performance was but little better, and the type was not further developed. One H.P. for 20 lb. was insufficient power, and bigger engines for the weight had to be used.

The Curtiss "H8," built in America, was better in this respect. Only one of these was made, but knowledge obtained in England during its construction was embodied in its successor, the "H12." Many H12's, with 340-h.p. Rolls-Royce engines, were used with success against submarines. The H12's weighed 5 tons, carried 5 persons and 500 lb. of bombs at 80 knots for 6 hours, and were armed with three or four machine-guns. They had 1 H.P. for every 16 lb. and when first used had a higher performance than any other sea-going aircraft over the North Sea. They showed that hydroplaneing efficiency, previously regarded as cardinal, could be sacrificed for sea-worthiness, provided sufficient engine-power were available.

All the earlier types, including the H8 and the H4's, were practically flat-bottomed, and powered heavily in disturbed water; the higher power available in the latter type enabled these seaplanes to take off rapidly and the improvement of providing them with a pronounced V-section bottom was adopted first on a small "America," and then on the H8 with the two Eagle engines.

This combination of Felixstowe hull, H8 wings with Rolls-Royce engines known as the F2 was the forerunner of all the many boat seaplanes of the latter part of the war. These craft, one of which is illustrated (see Plate II.), corresponded in size, weight and power to the H12 type, but on account of their V-section hulls, were capable of alighting in, and taking off from, disturbed water with less risk of damage to the hull. Their effectiveness against submarines led the Germans to evolve high-performance two-seater fighter seaplanes of the float type. Among the most effective of these were the Brandenburg mono- plane seaplanes. These remarkable craft became as a menace to the heavier "boat seaplanes," and as they were carrying only a light machine-gun load and comparatively little fuel they out-maneuvered them.

It has been seen that the small seaplane that might have countered these was not developed in England. The defensive armament of the large seaplanes was increased, though such additional load adversely affected their performance and sea-going qualities. Small two-seater seaplanes to escort the larger ones were constructed, but as these were not delivered until after the cessation of hostilities, the technical advantages to be derived from this new field of study were only partly reaped. Summarizing the above we see that the smaller boat seaplane originated in France, the large one in the United States of America, the very large one in England. Many seaplanes were brought to England from America, were improved by experience obtained in Britain, and subsequently the types designed at Felixstowe and built in England were reproduced in America in quantities.

The construction of the American "NC" type, and its crossing of the Atlantic, was a wonderful achievement. The fact that from lack of fuel "NC2" alighted in mid-Atlantic, and arrived at Ponta Delgada after travelling 180 sea miles on the water in 54 hours with bad weather, pays a high tribute to the design and is a sign of the future value of the seaplane in commercial transport.

In France the war incentive to seaplane progress was lacking. France has mainly used the small boat seaplane for coast defence, and has been up to the present using only high-powered engines lacking for sea-going craft; the Hispano-Suiza 200-H.P. being in most general use.

In July 1914 the Germans had few seaplanes in service, and of these one had been imported from England. They were nearly all of the two-float type, and suffered from the defects of that type previously mentioned. Their activities were mainly defensive, and did not require either long endurance or good seaworthiness. Torpedo-carrying seaplanes were made use of in
1916 from the Belgian coast in attacks on merchant shipping, but these were not required to cover great distances, and were not remarkable. Isolated small boat seaplanes have been constructed in Germany, but not in quantity.

The Germans (no doubt in consequence of their greater study of airships) continuously kept a heavier, and more reliable, engine than the Allies, but (consequent on 1917) the small produced high-powered units, and it is probable that these two facts are mainly responsible for the German retention of the smaller "float seaplane." Moreover, their engine failures at sea were few, and there was not, therefore, so much pressure for their seaplanes to withstand open sea conditions.

The Brandenburg seaplanes of 1917-18 had rather heavy engines of 180 to 200 H.P., yet they had very high performance. Their success in fighting was due to the unusual monoplane wing arrangement which gave a clear field of fire in all directions above the horizontal plane, and to their clean general design without any external wire bracing. They employed the more recent type of twin floats.

Before the period of limitation of aircraft construction set by the Allied Commission of Aeronautical Control, the Germans had been developing the giant aeroplane in several experimental forms, differing mainly in the arrangement of multiple-engine units. These ranged in total weight roughly from 9 to 12 tons, and in the case of the larger types difficulty was experienced in providing sufficient area of contact between the wheels and ground. This difficulty did not exist in the giant seaplanes, a few of which have been built in Germany for Lake Constance. Their aerodynamic design was not good, and the type was not perpetuated in its original great size on account, probably, of difficulties of control. The Staakgen Giant was another example; this had two long floats made entirely of duralumin. These giant seaplanes would no doubt have developed but for the prohibition, and an interesting comparison of advantages would have been obtainable between the giant seaplane, and the giant aeroplane.

Characteristics of Seaplanes.—The boat seaplane, a craft suitable for less-sheltered waters than the early float-equipped aeroplane or hydro-aeroplane as it was called, must, to be of real value in naval operations, be fully sea-worthy, and such progress as had been made had not yet proved by 1921 whether this was completely obtainable. But there were then—(1) the smaller craft to operate from sheltered waters, rivers and lakes, and (2) the boat seaplane to operate over sea. The first includes all types of small dimensions of less than, say, 4 tons, (3) "float boat" types in 1921 fell into this category. To the considerations of design, stability, and control applying to aeroplanes must be added the design and distribution of the float system, so that the forces due to water shall not affect adversely the stability and control. These water forces are handled very satisfactorily by the aerodynamic elements, which are ineffective except at the higher hydroplaning speeds. Hence the float system must be such that any instability that occurs between the airborne and waterborne conditions may take place at speeds high enough for the air controls to be dominant.

Wheeled seaplanes, for land and sea alighting, had been built by 1917 as experiments, but their development had only just begun. Their wheel system, springing, ground clearance and like factors are those of the aeroplane. These amphibians are handicapped by the weight of the float system, but show promise of very useful speed and climb.

Most large centres of population possess areas of smooth water, rivers, lakes or harbour, affording an alighting area comparable with the average aerodrome, and if the proposed route provides large water surfaces, making this fact can be taken advantage of by carrying a heavier load per sq. ft. of wing area with a corresponding gain of speed, reduction of structure-weight and increase of efficiency.

The desiderata for seaplanes for the open sea are less well known, and more difficult of attainment. They must for sea-worthiness be large. They had reached 15 tons by 1921 and were still far below the size of existing "float boat" types in 1921. The limiting factor in some cases required to three and a half. The increase of wing-loading, though it entails a higher stalling speed, and the adoption of a wing-section of high lift, may yet improve matters. The desiderata for a high speed are not so essential as for war, and modern naval vessels are capable of over 30 knots. A high speed is not so essential as for war, and modern models are capable in a few cases of 300 and over.

The reduced area of wings so obtained has kept down the structure weight. For war the wing, whose camber is variable to give high speed with good lift at low speed may be perfect. The arrangements of the seaplane wings, in all, the engine, crew and loads are carried in one or more fuselages well above the floats in such a way as to bring the centre of gravity and thrust axis into approximate alignment.

(a) Two main floats which together support the whole weight and provide lateral and longitudinal support. (b) Two main floats together with one or more tail floats, the former supporting nearly the whole weight, but being dependent on the latter for lateral and longitudinal support. (c) One central main float supporting the whole weight and providing longitudinal support, two comparatively small wing floats providing lateral support.

1921 probably, a 15-ton seaplane of the type (a) and (b) provide positive metacentric height both longitudinally and transversely, while system (c) is always dependent on the wing floats for lateral support; for small angles of roll this is lacking, as it is necessary to carry the wing floats clear of the water when the float seaplane is on an even keel.

Systems (a) and (b) are most usually employed because they avoid this defect, A main advantage of the system (c) is that the float impedes the view much less. Arrangement (a) is better than (b), as the tail float of (c) is easily damaged, and thereupon longitudinal support being lost, the seaplane turns over on its back.

Float seaplanes have the following merits over the boat-type:—(1) They can be handled on slipways with the most primitive arrangements, and can be beached safely on any smooth foreshore. (2) The aerodynamic elements give the normal balance, stability and control. (3) They may be convertible into aeroplanes, or vice versa. (4) The floats are simple in design, and can be subdivided into watertight compartments. (5) The static transverse stability of systems (a) and (b) enable the wings to be folded foro, for hoisting the craft from the water to a ship or a quay.

(a) For war, good areas of fire are obtainable over the rear hemisphere.

The following are the disadvantages:—

(1) The floats are uneconomical of structure-weight.

(2) The aerodynamic drag is comparatively high.

(3) The propulsive element is substantially reduced.

(4) The floats are simple in design, and can be subdivided into watertight compartments.

(5) The static transverse stability of systems (a) and (b) enable the wings to be folded, for hoisting the craft from the water to a ship or a quay.

(6) For war, good areas of fire are obtainable over the rear hemisphere.

The advantages of the type are as follows:—

(1) An excellent crew position for flying and observation, e.g., in anti-submarine operations.

(2) Comfort: the crew can move about, the pilot be relieved, etc.

(3) Economy of structure-weight.

(4) A purpose-designed centre of gravity, and consequently the hull weight.

(5) Absence of racking forces, and large size possible. This last advantage is the most important, and the limit of size of aircraft, as already discussed in the section on "aeroplane design," applies here as regards the hull. In practice the hull weight do not increase even in the same proportion as the total displacement, a slight reduction in the ratio of the hull weight to total weight having been obtained, and if this continues further, it is clear that a reduction in hull weight can be set off against an increase in wing weight, resulting possibly in the most economical scale being greater than anything yet constructed.

The disadvantages are:

(1) The wings cannot be folded or stowed.

(2) They cannot be beached except in very soft mud, and requires elaborate apparatus to move it to a shed on shore.

(3) They must be handled from aeroplanes, etc.

(4) The large distance between the centre of gravity and the thrust axis, and the low position of the centre of gravity in relation to the centre of lift. The former produces a variable pitch moment, the latter influences adversely the lateral control.

Elements of Design Peculiar to Seaplanes.—Many of the desiderata in a seaplane design are antagonistic to each other.

Flight can be achieved with 1 H.P. for each 25 lb. to be flown, but generally 2 H.P. for each 40 lb.; for ship or 10 lb.; therefore, structure-weight must be economized.

No wings can stand a blow from any large volume of water. The wings must clear the waves and any but light spray. Regarded as a whole the and the centre of pressure of the wings should be nearly coincident, and for this the centre of gravity should be high above the water. As a watercraft, however, a seaplane is in a fairly low position, and the centre of gravity is needed in relation to the waterplane. The compromise necessary puts the centre of gravity so that the metacentric height (apart from the wingtip floats) is negative.
The position of the aircrew dominates the design. Air inflow near the blade-tips sucks spray off the sea, and picks up spray thrown by the hull, with damage to the blades. This is prevented either by protecting the blades with a cover or over some part of the structure, e.g. lower wing or hull. This places the thrust axis well above the centre of gravity, and the smaller the seaplane, the more this effect is notable.

Here the high thrust axis produces a downward pitch varying from zero in gliding flight to a maximum at full power. In the earlier boat seaplane this was incorrect, and, in order to get balance in normal flight, the craft was very “tail heavy” when gliding. This was diminished by using the tail plane in the slipstream, by setting it at a negative angle to the chord of the main planes, and by distributing the weights so as to bring the centre of gravity particularly far forward. The thrust-couple thus opposed by these means is overcome. Gravity, therefore, by the center of gravity being delayed until the air-controls were effective, and while in the full scale, no instability was apparent, probably on account of the damping action of the air-surfaces, since the seaplane took the air without operation of the controls by the flier.

A somewhat similar model of a much larger seaplane with steps 32 ft. apart was stable throughout the speed range. In the small types the hump lengthens the distance apart of the steps. The two steps may be compared to the wings and tail surfaces of an aeroplane; the main step nearly under the C.G. does the lifting of the boat on to the surface, while the rear step provides the balance and also resists the normal tendency to lift away on the forward motion. This is the only possible arrangement in such a way that the intermediate hull-sections and that part of the hull carrying the tail surfaces, of the rear step, are clear of the two depressions formed in the water by the passage of the hull. It is not possible to make such steps go through the water, the total resistance is equal to the sum of the two resistances, and this is increased if both are required to be very shallow. If however, the step, to the minimum necessary (at the rear step itself) to give stable conditions. This best arrangement can only be obtained, at present, by individual model experiments. The full scale has considerable applications for the study of the moment of resistance on the hull, which can be reproduced artificially. Tests show that complete 50 ft. steps on the model would be more than 50% deeper than in the full scale, hence the seaplane corresponding to a stable model may be fully relied upon.

The absorption of water reactions on a badly designed hull may continue to be considerable up to the moment of quitting the water; then, their sudden disappearance may produce moments dangerous at a time when their correction by air-controls requires big movements. Such a seaplane at a high speed on water, and kept to the angle for maximum lift of the wings by means of the air-controls, is subject to a moment in pitch due to the water reaction on the steps. This is balanced by a moment due to the elevator of the seaplane, but the elevator will not be sharp enough to counter the moment, which had been applied by the rudder while the seaplane was in the water. If however, the rudder can be used with the same degree of freedom, the water reaction will be of no moment.

To keep hull weight low there are special methods of construction. The timbers used in boat-building practice have so far been found best. In the present sizes steel is out of the question. Aluminium that has been used in German high-speed planes in the usual manner is essential for watertightness and durability. In any case of timber, mahogany is the best for this purpose.

Unsuccessful attempts have been made to depart from the time-worn principles and practice of light boat building. A planked skin is often attempted to meet the water load. The hull is built in two sections, the middle part being an integral part of the deck, and the outer part being carried on a framework. The framework has to be made rigid, flanking the whole. The skin is of wood, and is covered with a watertight material. This method has been tried with the purpose of gaining a lighter hull, and the hulls must, therefore, be stable over the whole range of water speeds.
AERONAUTICS

53

ing members. Two or more thicknesses of mahogany-planking are
through-fastened to transverse timbers of small section closely spaced;
these are connected longitudinally by a large number of stringers of
rectangular section lying in a radial plane, edge on to the timbers;
though these stringers are in turn supported on their inner edges by bulk
hogs of comparatively heavy section widely spaced. The small section
timbers are placed so closely that no fastenings need be passed
through the skin anywhere between timbers. This type is water-
tight, durable and cheap. The average hull weighs not more than
11½% to 12½% of its displacement.

The flexibility absorbs the shocks of alighting and taking off, and
precludes heavy local pressures. Care is taken to distribute the air
loads, which are generally concentrated along two lines transversely
to the axis of the hull, over a sufficient area of the skin, and all
internal installation is arranged to allow for comparatively large
relative movements of components. Transverse subdivision is prac-
tically impossible, but the provision of a subdivided double bottom
is easy and effective.

Seaplane in Operation.—The preparations made for housing and
upkeep of seaplanes were unfortunately dominated by the require-
ments of the early types. The seaplane station was modelled on
aerodrome lines, with the addition of a slipway to the water. The
flat floats of the float seaplanes were placed on trolleys, and thence
by slipways to the water. The delicate V-sections of the heavy
boat seaplane is ill-suited for such handling. The draught of the
modern boat (with a full hull) it exceeds what can be negotiated by
men in waders. If such boats are to be brought ashore at all new
lands are required for doing so. Experience shows that boats of
only 5 or 6 tons are damaged in such handling, though they draw
little more than 2 ft. of water. To limit the bringing ashore to slack
water periods in good weather, would be intolerable for commercial
work. Better water-side facilities, such as covered sheds with direct
access to the water for the construction, erection and repair of
modern seaplanes are needed. These should allow of admitting water
to part of the shed to reduce the out-of-water handling to a minimum.
As a large expanse of sheltered water is necessary, and the rise
and fall of the tide is important, floating sheds may be needed.

Close sheds are not essential for operating seaplanes. The larger
the seaplane the more can it resist exposure for long periods, and the
practice of mooring out will become an economical necessity, but
the seaplane must be designed with this in view, and proper auxiliary
services for heating, fueling and repairs provided. In high winds
seaplanes moored out have risen off the water at their moorings
and destroyed themselves, but this is avoidable by destroying the air-flow
over the lower planes by attaching light boarding along the leading
edges at a large negative angle to the chord. As the seaplane for com-
merce has been but little studied, marked developments may be
expected in this direction; sea-worthiness is still the main problem for
warcraft and increase of size the most direct solution.

For operation from smooth waters structure-weight and hull
weight can be reduced and wing load increased, while high-lift wing
sections also offer much promise.

It is remarkable that though the viewpoint for seaplanes is so
different from that for aeroplanes, the reliable engine unit is equally
found to be the prime desideratum for present progress. (A. J. M.)

IX. AIRSHIPS

Airships are divided into three main types:—(1) The rigid, which
has a hull structure of rigid members covered by an outer fabric
fairing, and containing a number of separate gas cells. (2) The
semi-rigid, in which the whole or part of the bending and longi-
tudinal compression induced in the ship by the rigging wires is
taken by a rigid keel. The envelope from which this keel is
carried is kept distended by the pressure of the gas, but is mainly
subject to vertical loads. (3) The non-rigid, in which the envelope
maintains its shape solely on account of an internal pressure
which must exceed the outside pressure.

Small airships up to, say, 300 ft. long are necessarily non-rigid,
as there is not sufficient lift to justify a rigid framework. The
largest airships have a rigid hull structure because the pressures
involved in an envelope of large diameter necessitate very heavy
fabric and make a system of compartments essential. Between
the two, the semi-rigid seeks to reduce the fabric tensions by the
use of a rigid keel girder, but it is doubtful whether this justifies
the keel, except as a convenient means of carrying the loads
from the envelope.

A rigid airship has a hull structure of light aluminium girders,
arraigned with some 25 longitudinals connecting some 17 main
transverse polygonal rings. At each main ring a bulkhead is
formed of the load wires which suspend the weight of the keel
from the upper part of the framework and the radial and chord
wires which retain the shape of cross section of the ship. A
specially strong keel of triangular section and some 8 ft. high runs
nearly the whole length of the ship and carries the petrol tanks,
water-ballast bags and other weights, being itself supported
at the main transverse rings. The 30-metre spaces between the
bulkheads are each fitted with a single gasbag of gas-tight
fabric. The degree of fullness of these bags varies from the
maximum to sometimes less than 50% full, when the upper parts
of the space alone will be occupied by the bag, whose lower part
is collapsed and empty. A cover of fabric is stretched over the
outside of the whole frame, so as to present a smooth surface and
protect the gasbags from weather and light. Separate engine
cars are attached below the hull at points along its length.

* Total weight carried for performance shown.
The early development of rigid airships was carried out by Count Zeppelin in Germany, and represents an extraordinary record of perseverance. This development was only rendered possible by political influence and by the repeated financial assistance available. The Schütte-Lanz airships were of wooden construction and developed more slowly. They appear, however, to have embodied considerably more original and perhaps courageous developments than did the Zeppelins, which were developed more as gradual minor improvements on the original design.

British Rigid Airship No. 1 was started in 1900. During the construction great consideration was given to the various auxiliary gear required by the ship and to the problems included in the handling and mooring as well as the actual flying of the ship. The thoroughness and accuracy with which this auxiliary work was developed is most remarkable in the light of later experience. Before the first flight was made the ship was moored by the bow to a mast with her cars resting on the water. The ship was broken amidships in Sept. 1911 as the result of a mistake in handling while she was being returned to her shed after one of the trials of handling before flight. Comparison of the details and estimated performance of this ship with the contemporary Zeppelins shows that she was a remarkably good first design and that had it not been decided to abandon rigid-airship construction the British development of these ships would almost certainly have become at least equal to that of Germany.

British Rigid Airship R9, by Vickers, stopped at the beginning of the World War, was restarted in July 1915 and made her first flight in Nov. 1916. She made a rather remarkable passage to Howden through a snowstorm over the Pennine range. Being somewhat inadequate in buoyancy, she was used for instruction and ultimately for mooring experiments.

She was followed by four ships of R23 class, built by Vickers, Beardmore and Armstrong, and again by R27 and R29, which were remarkable for the absence of the keel which had existed in all previous rigid airships and had been looked upon as constituting the real strength of the ship to resist bending and shearing forces. This keel subsequently reappeared in German Zeppelins and in the ships built in England, but then merely as a means of distributing to the main frames the weights of petrol tanks, etc., arranged along it.

Two wooden ships, R31 and R32, were built by Short to a design closely similar to that of the Schütte-Lanz type. They were considerably faster than contemporary ships.

Rigid-airship construction in Germany had advanced continuously and was, therefore, greatly ahead of French and British. A combination of the talent and experience of the Zeppelin and Schütte-Lanz firms early in 1916 resulted in the design of L20, giving a speed and performance far ahead of any earlier ships. L33 of this class was brought down in Sept. 1916 in such a comparatively undamaged condition that it was possible from her to prepare a design in England to which R33 and R34 were built. These ships were not, however, completed till late in 1918.

The German L65 class marked a further advance in speed and performance, while the L70 class, of which the first ship, L70, was destroyed on the first flight to England with some of the chief constructional experts on board, marked still further progress in performance and in the simplification of the machinery installation, in the adoption of fins of triangular cross section. L72, which was not actually completed until after the Armistice, had again a slightly higher performance.

After the Armistice Germany built a much smaller airship, the 'Bodensee,' for commercial purposes, and with her carried out a remarkable series of passenger flights. The ship was then enlarged and a sister ship, 'Nordstern,' also constructed.

Subsequent to the R33 class the British R36 and R37 were constructed to a generally similar design, of somewhat greater capacity and much improved detail. R50, designed and constructed by Vickers, embodied several entirely new features, but her size was so restricted by the dimensions of the construction shed that her performance was seriously handicapped. R38 made radical changes in features of design, and a clear and definite departure from German methods. The United States had contracted for its purchase. It was to be used, as it was generally understood, for an experimental service from New York to San Francisco and for that purpose masts and intermediate stations were being prepared. R38, while on the final test flight before delivery on August 24, 1911, caught fire and fell owing to structural weakness, and many lives were lost.

Non-Rigid Airships.—In 1913 the chief general classes of non-rigid airships were:—(1) Those with a plain circular envelope from which the car, etc., was suspended from special fittings on
AERONAUTICS

the envelope, and of which the British military airships are typical. (2) The Parseval type, in which the circular envelope is reinforced against bending under the rigging tension by Parseval trajectory bands passing over the envelope and secured to a girdle to which the car is rigged. (3) The Torres type, made by the Astra firm of Paris, trilobe in section, with riggings led inside the envelope and divided into fans secured to points along the two top ridges. The two latter systems are intended to decrease the distance between the envelope and the car without producing excessive tendency to bend in a large ship.

At the beginning of the war the French had several non-rigid ships of various types which carried out bombing operations, but no important new ships were built. Germany had a few Parseval airships, which did a little work on the Russian front, but there was no important development of small ships. England had three small non-rigid, also one Parseval and one Astra. It became necessary, however, at the beginning of 1915 to develop the very small non-rigid airship as rapidly as possible as an anti-submarine protection. Extreme simplicity was essential in order to allow of rapid production by firms having no previous experience. For the first 30 ships aeroplane bodies were used as cars, but later special cars far more suitable for patrol work were adopted. Engines of about 90 H.P. were used and a crew of three carried. Some 150 ships of the S.S. classes were built, but at the end of the war it had been decided to adopt a slightly larger ship with twin engines and a crew of five as being more suitable for the longer patrols which became necessary. Later in 1915 a larger type—the Coastal class—having greater speed and taking a crew of five, was built. For these the Astra system of rigging was adopted in order to reduce to a minimum the necessary height of the girdle. Thirty-five of these ships and ten of an improved (C*) class were built during the war. These ships later carried a crew of five and had an endurance of 12 hours at a full speed of 51 knots. In 1916 the first ship of the North Sea type was flown. This class was intended to work with the fleet and had an endurance of some 24 hours at 50 knots. Sixteen of these ships were built.

The characteristic of these ships, more particularly the N.S. class, was that the petrol tanks and all other weights possible were carried direct on the envelope. In the N.S. class the car was separate from the power unit and the weight distributed over the ship. This gave important advantages over all earlier non-rigid where the loads had been concentrated in the car. The S.S., Coastal and N.S. classes were all designed and built at the R.N. Airship Station, Kingsnorth. They constitute a very interesting development from the small supply of ships and experience available at the beginning of the war.

A considerable number of British non-rigid airships were built and supplied to the French, Italian, Russian and American services, and one Italian semi-rigid was supplied to England for experiment. A large Astra ship of some 800,000 cub. ft. capacity was built in France with two large cars. It is understood that lack of longitudinal rigidity of the envelope gave trouble.

The Italian airship design has favoured the semi-rigid type of construction, their most successful type being one in which the keel girder was not in itself rigid but  vertebrae**, consisting of a number of pin-jointed frames capable of taking the longitudinal thrust induced by the car rigging, so long as the envelope held the keel in line. This system did not greatly reduce the height of the ship, as the points of attachment of the rigging were necessarily at the bottom of the envelope instead of near the level of its centre line. It did, however, enable a much lower envelope pressure to be used than in the non-rigs of the same size. This enabled a very light envelope fabric to be used and also a system of automatic pressure regulation by air taken at the nose of the airship. These ships were designed for bombing raids at great heights across the Adriatic Sea. The excellent weather conditions rendered their comparatively slow speed quite satisfactory.

Germany built a few large semi-rigids of the M type and the Parseval type. The two largest, PL26 and 27, were of some 1,120,000 cub. ft. capacity. They embodied many interesting features, including spherical partitions which divided the envelope into sections so that the accumulation of pressure at the upper end of the ship when pitched was avoided. As far as is known, no very thorough trial of these ships was made, but as far as the experiment was carried it appears to have been satisfactory. The type was not, however, proceeded with on account of the decision to concentrate on the rigid type.

Italy, after the Armistice, built a large semi-rigid "Roma," designed for transatlantic service.

An interesting aircraft which was developed experimentally as a counter to the Zeppelin raids was the "airship-plane" devised by Wing Comm. Usborne. A complete aeroplane was rigged under the envelope of an S.S. airship in such a way that, after patrolling at a great height, the envelope could be released and the aeroplane left free to deliver its attack. After several preliminary flights the first attempt to slip the envelope in flight failed on account, probably, of temporary loss of pressure in the envelope. The machine was partly released prematurely, and was damaged as it fell away; Wing Comm. Usborne and Wing Comm. Ireland were both killed. The former particularly was a most serious loss, as he had up to that time been mainly responsible for the exceptionally rapid airship development.

**Kite Balloons.**—The Drachen kite balloon, in the form originally used by Maj. von Parseval and Capt. von Sigsfeld in 1896, was used by the Germans immediately on the declaration of war for observation of artillery fire. Its value became at once apparent, and it was immediately copied by the Allies, very large numbers being made. The stability was, however, so poor that this type could only be used in fair weather, and accurate observation was often difficult. Capt. Caquot of the French army designed an improved arrangement of stabilizers. Three fins, one at the bottom of the tail and two 120° from it, were in the summer of 1916 ultimately adopted instead of the single fin of the Drachen and the string of parachutes which were necessary with it. Considerably improved stability was obtained, and there was an important increase of the dynamic lift which gave increased height. This type was generally adopted by the Allies for military use and worked well up to 6,000 feet. The same type of balloon was used by the navy, but was replaced by a similar one designed to resist higher wind speeds and capable of only 2,000 feet. This was used extensively by the fleet for garrison purposes and as a lookout. The balloons, being in continuous telephonic communication with the captain of the ship, could transmit information more completely and rapidly than other aircraft. The balloons were also used in the ships protecting convoys, although it was sometimes contended that they acted as buoys to show the position of the convoy to a submarine which could thereby keep in touch at a safe distance during the day and deliver its attack at night. These naval balloons were capable of very high wind speeds, in one instance 80 knots being recorded.

An Italian A.P. type of balloon having a considerably smaller length to diameter ratio was adopted to give very great static lift in calm air. These were used for the apron defence against aeroplane attack. A line of balloons lifted to a height of some 15,000 ft. a horizontal cable from which hung thin vertical wires arranged to foul the wings of the hostile aircraft.

**Airship Operations.**—During the early days of the war French airships were employed for bombing behind the German line, but the damage to the ships, usually through gas leakage caused by shell and bullets, was so great that only a limited amount of work was done.

The Italian airships designed specially for bombing raids at very high altitude across the Adriatic obtained considerable protection from their height, and more useful results appear to have been achieved.

The Zeppelin raids over England were an interesting achievement from the airship point of view. So much of the effect of these raids was indirect, in the delays to munition work during raid nights, large amount of personnel and material retained for defence, and also in the psychological effect produced, that it is
impossible to assess the full value of this work as a warlike operation.

A less well-known Zeppelin activity was the patrol of the North Sea in conjunction with the navy. These patrols were of extraordinary extent and thoroughness, and must have proved a most valuable assistance to the naval authorities. The value of a similarly thorough patrol to the British would probably have been even greater. British airship activity was confined almost entirely to anti-submarine work carried out by non-rigid ships partly as patrols over definite areas and partly as protection to convoys. As a prevention to submarine activity these small ships were extremely effective, although the number of submarines actually destroyed through their direct agency was small. The use of a hydrophone from an airship while in flight was being successfully developed at the time of the Armistice, and promised greatly to increase the effectiveness of their work. The function of these ships was to detect and keep touch with the submarine until the surface craft arrived with better locating gear and a much more ample supply of explosive with which to carry out the actual destruction. The large ships did a certain amount of scouting work for the fleet, but this operation was really only in course of development at the time of the Armistice.

The number of hours flown on patrols was over 87,000 and the distance covered well over two million miles.

One remarkable operation by the Zeppelin L57 was her flight to East Africa for the relief of the German force there. She left April 17th and reached the East African coast on May 2nd. She flew 10,800 miles in 12 days, on 103 flying hours with four engines running at 174 to 180 revolutions per minute.

The German airship fleet totalled 28 ships, of which 13 had been built in the United States at a cost of about £4,000,000 each. The British fleet totalled 61 ships, of which 25 had been built in the United States at a cost of about £2,000,000 each.

The value of a similar operation to the British would probably have been even greater.

British airship activity was confined almost entirely to anti-submarine work carried out by non-rigid ships partly as patrols over definite areas and partly as protection to convoys. As a prevention to submarine activity these small ships were extremely effective, although the number of submarines actually destroyed through their direct agency was small. AERONAUTICS

R.36 AT HER MOORINGS.

S.S.Z.4 IN DOCK AT GODMERSHAM.

N.S.6.

CHANGING CREW.

TOWING C.I. FULL SPEED.
Jamboli (Bulgaria) at 4:20 A.M. on Nov. 21, 1917 with over ten tons of machine-guns, ammunition and medical stores. She had passed Khartoum when she was recalled and landed again at Jamboli at 5:30 A.M. Nov. 25, having covered 3,000 m. in 97 hr. with her full load of stores.

The Atlantic flight of R34 was slightly better in point of time. Leaving East Fortune, near Edinburgh, at 1:42 A.M. July 2, 1919, she reached New York at 1:54 P.M. on July 6 after 108 hr. 12 min. in the air. The return journey to Pulham in Norfolk occupied only 75 hrs.

The longest flight by an N.S. airship was 101 hours. The record for non-stop flight was 51 hr., equally remarkable when it is realized that the crew of three were continuously on duty.

As indicating the regularity of the patrols, it is interesting that in 1918 from Jan. to Nov. there were only eight days on which there was no airship patrol. As showing the life of a ship, that of Coastal No. 9 at her patrol station in Cornwall may be quoted. She was inflated on July 1, 1916, and deflated on Sept. 14, 1918. During this 805 days she flew 2,500 hr., or an average of 3 hr. 6 min. per day, over the whole period. The deduction to be drawn from the airship operations carried out appears to be that where their duties will be limited to those areas where intense hostile anti-aircraft fire or hostile aeroplanes are unlikely to be met. With this reservation their uses are likely to be the same as in the past war, with a very important extension to work over undeveloped country, the airships acting as patrol ships and for the transport of stores. The use of a large airship as a carrier from which fighting or bombing aeroplanes could be released, and to which they could return, was considered. An aeroplane was on two occasions dropped from a rigid airship with no inconvenience or danger to the pilot.

Arrangements for the complementary process of hooking on and releasing aeroplanes are being perfected. The time that this operation will take is the limitation.

For passenger and goods transport over distances longer than the aeroplane can profitably cover at one stage the airship has important advantages. By eliminating the time spent at intermediate stops and by flying day and night with the passengers in reasonable comfort, the effective speed over a long journey is probably greater than that of the aeroplane. To this must be added the ability to make long ocean passages in safety and so to select a course as to take advantage of trade winds or local meteorological conditions.

German commercial airship activity was already in 1911 very extensive in England and was only suspended by the restrictions of the Peace Treaty. The "Bodensee" had already carried out a remarkable series of flights between Berlin and Friedrichshafen, making 100 flights in 97 days and carrying in all 2,300 passengers. The ship has now been enlarged and a sister ship built in order to extend the flights to Scandinavia. Larger ships and an extension of the service to London and other capitals were contemplated, and a service of ships of considerably larger size from Cadiz to N. and S. America was planned.

Mooring and Handling.—The earliest activity of airships had been limited rather by the ability to handle them on the ground than by their ability to meet weather conditions in flight. British Rigid Airship No. 1 was moored by the bow to a mast and sheltered by a screen on Cavendish Dock, Barrow, before the ship was blown. This trial was successful, the ship remaining safe during winds with gusted speed up to 48 m. an hour. In the course of these trials the screen was abandoned.

The Royal Aircraft Factory in 1912 devised and used continuously for many months a new form of mooring mast to which a non-rigid airship was attached while floating in the air. To prevent the ship overriding the mast in gusty weather and to facilitate approach, the mast was provided with three cables attached to the top, into which the nose of the airship was drawn by a rope running down the inside of the mast. The cone was free to rotate about the axis of the mast as well as to rock vertically on a universal joint and the mast, functioned satisfactorily, save that side gusts caused the cone to rub the bows of the ship with a tendency to bend it. These mast moorings were the precursors of one of the great developments in aerodynamics and were adapted in 1912 by the R.A.F. at Pulham, and the mast of wire was, however, necessarily supported by the ship, and a large amount of static lift was therefore necessary. This system gave poor result in winds over 30 m. an hour. In the system for the wind a cone is dropped from its head to the ground which it is supposed to fit, and was able to take the ship and its load in winds up to 30 m. an hour.

Under war conditions this restriction was serious, and the method of the mooring mast was again examined. A non-rigid envelope rigged with a dummy car was secured to the head of a mast at Kingsnorth, first with a cone but later with the cone removed. The ship was allowed to take wind down to its lowest point and then to swing back, the tail making a small circle. The nose of the envelope was slotted and a spar, the after-end of which was supported by a cone of cords led slightly forward and secured round a circle on the inside of the envelope. The tension in the fabric of the envelope and in these cords was insufficient to prevent the envelope from being drawn back and consequently for stiffening the bow of the envelope while in flight and also for mooring.

A further set of experiments was carried out at Barrow with a ship secured to a short stump mast, attached to her mooring point and stepped on a lighter. The point of attachment was not on the axis. Indeed, it was allowed to be anywhere. The envelope was developed in such a way that the mast was always exactly vertical, the outer envelope being made taller than usual. A smaller mast was fitted with a horseshoe head, so that fittings carried at the top of its arms could be attached to suitably reinforced points of the envelope. This gave support against rolling, but the point of attachment was some distance aft on the ship, and consequently the steadiness was not quite so good as when the envelope was attached by its extreme bow point.

Definitely comparative tests between mooring at the nose, using the spars of the ship and the envelope and using the hrosehoe mast were carried out at Pulham. After considerable time the internal spar of the former broke, for a reason that was not explained, and the latter was found to be more effective. The results of this for mooring the small ships at advanced patrol stations, the horsehoe was little employed.

Mast mooring was, however, realized to be important for rigid airship. The "Longton" trials in 1918 showed that R34 secured the ship at Pulham were instituted in July 1919 with success. The ship later remained continuously at the mast for 70 days and experienced winds up to 35 with gusts of 45 m. per hour. Difficulty was experienced in lifting the ship from this mast, but at least some help was obtained by the action of the control of the winch which hails on the ship's wire. In the experiments with R24 a kite-balloon winch was emplaced and abandoned owing to its irregular action and control. For the experiments with R33 a steam shovelling engine was used temporarily and found to be satisfactory.

The process of landing the mast consists in the airship dropping down a rope supported by this arm and_{_} the other end of the rope led from the winch up the centre of the mast and down to the ground. The winch hauls in these ropes and draws the ship to the masthead. There is no difficulty until the ship comes within some 200 yards' distance of the mast. Below this distance it is found that the tendency of the ship to swing both sideways and fore and aft, under the influence of gusts of wind. This difficulty is less serious when the ship is trimmed somewhat down by the stern, so that the wind force is not so great. The wire is arranged in a long diagonal line from the masthead. At the point of attachment to the wire, which is one of the essential pieces, a dummy mast is erected, and the "six-wire" system is employed, by means of which the ship can be lifted to the masthead. If this arrangement is not made, the variation in the wind force causes swinging of the bow of the ship, and a tendency to over sideways. With the ship trimmed considerably down, there was still, owing to disturbed conditions, a distinct tendency to swing, and it was often desirable to employ side-guys led from the bow of the ship to fixed points on the ground, in order to guide the bow to the masthead. With these arrangements, it was possible to secure a 60-ton ship to the head of the mast in winds of 40 m. an hour, with not more than eight men in addition to those actually in the ship. Pulham were therefore repeated on an approximating underground engine, and the engine was hoisted out and replaced by a spar, and a gasbag was detached and replaced by a spare.

Three-Wire System of Mooring.—As an alternative to the system of mooring an airship to a mast, and as a more temporary arrangement, the "three-wire system" was developed from one in which the ship was secured by her mooring-point to the head of a pyramid formed by three wires. These were attached to the mast and secured to the points of an equilateral triangle of some 800 ft. side. The height of the apex was arranged to be between 100 and 200 ft. in order that the downward component of the wires when resisting the wind should be zero. The ship should be moored in such a way that the wire was, however, necessarily supported by the ship, and a large amount of static lift was therefore necessary. This system gave very poor result in winds over 30 m. an hour, and was unable to take the ship and its load in winds up to 30 m. an hour.
there is, therefore, a tendency for the lee wire to go slack. When the
gust ceases and this wire draws taut, a serious impulse is brought on
the bow of the ship.

It was also found that the wires of this system were so nearly
horizontal that they formed the rim of R.A.

To overcome these difficulties, a running system was devised.
Various alternative forms were tried giving varying degrees of
rigidity of support. The final system which has been found most
satisfactory is that shown in fig. 26. This has the additional advan-
tage that only the comparatively short wires, SA, SB, and SC, are
carried in the ship, the remainder of the wires lying on the ground
and being picked up when the ship lands. Complete experiments with
this method found that a ship could withstand any ordinary wind forces
when secured in this way. She would be much more difficult to secure in
this way than the ship could not be easily supplied with water ballast, fuel
or additional gas.

In order to meet the greatly increased requirements for small air-
ships for anti-submarine patrol during the war, a system of mooring-
out grounds had been developed. These mooring-out stations were
formed by making clearings in suitable woods and cutting a comparatively
narrow avenue through the wood to the clearing. Small airships
were secured in these clearings, and re-fuelled and repaired in exactly
the same way as in other sheds. The protection was so good that
the ships were totally undamaged even though winds of 60 m.
an hour were blowing over the top of the wood at the time.

Airship Sheds.—The construction of airship sheds has been an
important item in the expense of airship work. The cost of the shed
increases very rapidly with height and with the span, both of which
must be considerable with any very small ships. Apart from
the cost of the shed, there is considerable difficulty in taking a ship
into the shed in any but very calm weather. When a wind is blowing
across the mouth of the shed, the airship has to be hauled broadside
on to the wind in order to pass through the door, and this represents
an operation when the wind is strong, strength or of a gusty nature.
In order to afford protection during this operation, all early airship
sheds were provided with wind-screens running from the corners of the shed outwards parallel to the
shore. These were of corrugated iron in which 30 ft. of the sheeting
had been omitted. These screens, although they reduced the horizontal wind
to a smaller extent than the solid screens, avoided the serious vertical
air disturbance and were, for that reason, considerably preferable.

Experience in Germany had, however, shown that a system of
rails provided with easily running trolleys was the most satisfactory
system of supporting the ship against sideways forces. These rails
run out from the corners of the shed parallel to the axis, and the
ship is driven by means of small ships, called trolleys running on these
rails. The support of the ship obtained in this way is so good that
wind-screens are rendered unnecessary, and the vertical air distur-
bance is considerably reduced. This system is that in which the use of
the system of handling rails, the housing of an airship presents considerable
difficulties. A landing party of several hundred men is required to
receive a 60-ton airship on the landing ground, to carry her to the
end of the handling ends and to build her round parallel to the rails.
The air in the neighbourhood of the shed is necessarily so disturbed
that considerably greater difficulty is experienced near the shed than
when on the open landing ground or in the neighbourhood of a mooring
mast. The difficulties connected with airship sheds are therefore,
considered to be so great that the shed must only be regarded as the dock, the mooring mast being regarded as the normal method of
securing an airship between flights.

When secured to the mast the airship can be supplied with gas,
water ballast and fuel. The passengers can be passed up the mast
by a lift and can walk through the bow of the ship down to the cabin.
The airship appears to behave satisfactorily in any wind. The most
difficult conditions to meet are those in which there is no wind but
rapid changes of temperature which affect the lift of the ship.

This necessitates rapid adjustment of the ballast in the ship by
taking in or discharging water. As long as there is a considerable
wind, the problem of the trim can be left to the wind.
gas cells is eliminated as far as possible. A certain amount of light is necessary in the keel, and this usually enters through the bottom twine holes of the outer layer. Densities of the N.S.S. of 50 plies are not uncommon, and the surface of the dope should be water-resistant in order to reduce the weight of water taken up in a rainstorm.

The fabric usually employed for the outer cover is linen weighing about 15 lb./100 sq. yards. This material is made up at the loom in a direction of warp which is perpendicular to the diagonal in the manner of a keel, and it is woven in such a manner as to give rather better gasstickness for a given weight. The German method is to build up the skins into large sheets some 10 metres wide and of length equal to the circumference of the bag. Fabric is then stuck to these sheets with a form of gelatin adhesive. Skin contracts as it dries, whereas fabric contracts as it absorbs moisture; great care has, therefore, to be taken that the fabric is attached to the skin without any deformation. The fabric loss of 10% to 15% is used as the adhesive is found to give trouble in hot climates, owing to the serious contraction of the skins and the softening of the adhesive just when good adhesion is most essential.

The tensile strength of a good fabric of this kind is about 15 lb./in./min. It is, however, necessary to consider the fact that the use of rubber in gasbags forms a non-conducting surface apt to become electrically charged by friction in the vicinity of an electric storm. The use of rubber has, therefore, been abandoned in Germany since very early days.

Fabric made with glue adhesive appears satisfactory even under the most extreme tropical heat.

For rigid or semi-rigid ship, in addition to being gasstich, must have an outer surface capable of giving protection against light and heat. It is also called upon to take very considerable tensile stresses. These are due partly to local tensions in the fabric, partly to the elongation and contraction of the envelope as a whole, but mainly to the internal pressure which is necessary in order to maintain the shape of this class of ship. When the ship takes up a steep angle of pitch there is considerable accumulation of pressure which, before the load can be removed, the pilot allows the pressure to become excessive the tension in the envelope is more likely to approach the safe maximum than from any other cause. The tension induced by internal pressures of air is still further increased by the load that, although not very suddenly applied—the interval between normal and maximum being at least 15 seconds—cannot be expected to be immediately released. The resistance of fabric to tension varies greatly with the rate at which the load is applied. For a high rate of loading—say, 150 Ib./in./min., the load reached before failure is 10 to 20% higher than the load reached with the comparatively slow rate of 5 lb./in./min. A load sustained for really long periods gives lower strength still. A load of only 50 to 60% of that which the material will stand for, say, 10 minutes will break it after a few seconds. Correct knowledge on these points is still required, but they are probably due to the manner of failure of a woven material, being one of gradual slipping of the fibres of the twisted thread.

A small local cut produces considerable reduction of tensile strength of an ordinary fabric. This is due to the concentration of stress at the ends of the cut causing the failure of individual threads in succession. Provided the cut is more than 1/16 in. long across the direction of tension the reduction of strength is not very considerable, but it is much more pronounced when the cut is made in the direction of warp. The unwound strength and is no greater until the size of the cut is such that it becomes an important proportion of the whole width of fabric in tension. In order to reduce the tension not only in the diameter of 2 or 3 cm., but also in the vertical direction in which one has its threads at 45° to those of the other planes which lie along and normal to the direction of tension. The threads of the diagonal ply are particularly liable to this trouble as no amount of tension in the diagonal ply will prevent the stress to which the ends of the cut. The extent of this reinforcement depends upon the comparative strength of the diagonal ply and upon the nature of the material with which the plies are stuck together. The table shows origins, size, etc., for the diagonal ply and for the single plies which are not unfavourable to underestimate the strength of typical airship fabrics built up of one or more plies of the same cotton and expressed as percentages of that of single ply, the adhesive being in each case rubber.

Rubber is particularly suitable as a doubling adhesive as it allows the requisite movement of threads for the reinforcement to take place. Glue, being a much more rigid adhesive, will allow of practical reinforcing actions for only a limited extent. Rubber is also a reasonably good gasproofing material and as it combines these qualities it is almost universally employed in the construction of non-rigid airship envelopes. The fabric used for the envelope of the N.S.S. is ordinary rubber of a thickness weighing 80 grms./sq. metre. The outer surface as a protection from light and heat was of 50 grms. of rubber containing a proportion of black litharge and a surface of aluminium powder. Between the outer and diagonal ply was 30 grms. of rubber and after the diagonal and inner ply 100 grms. of rubber as a gasstich layer; some more recent experiments show that additional protection is given to the fabric by back coating with a water-repellent substance.

Gastickness of most materials decreases considerably (4 or 5% per degree Centigrade) with increases of temperature. A film of gelatin gives the greatest gasstickness for a given weight, but its application requires of more careful control than rubber and offers considerable difficulty which has only recently been achieved with any degree of success.

An extract of the plum, cordia myxa or Turkish birdlime, has been introduced in some cases, but it has not yet been very successfully developed.

It is important to realize that gasstich fabric for airships must primarily stop the leakage of air into the gas. Loss of hydrogen is too small to be important, but the ingress of a weight of air definitely means a reduction in lift, which, unless counteracted, will lead to the abandonment of a ship. The greatest length of flight of the airship made fuel economy and some other characteristics of greater importance in the airship are dependent upon a very long period of hesitation, and the war followed by difficulties of supply during the war caused the airship to use, not a special engine suitable for this requirement, but standard aeroplane engines. This general unsuitability of the engines used for airships makes it to be by far the most unreliable part of the airship as a patrol unit.

The advent of the commercial aeroplane for long flights is in turn bringing a requirement more nearly that of the airship. Even 200 Ib./h.p. is now asked for. Compared with the airship which flies 100 hrs. on one load of fuel, a machinery installation which weighs, say, 5 lb. per H.P. burns 0·5 lb. of fuel per H.P. in one hour. An aeroplane in 10 hrs. will burn a weight of fuel equal to that of its machinery. In 100 hrs. an airship will burn ten times its machinery weight. The importance of saving fuel even at the expense of increased machinery weight is therefore much greater in the airship. During much of the airship's flight some engines are run at considerably less than their full power, thus introducing the need for good fuel economy at reduced power. In an airship repairs of some magnitude can be made in flight (a cylinder has been changed, and a new engine put in). It is said that the war has not yet been flown this, as the time of the revolutions for full speed over which the airship engine was driven.

Belts, chains, bevel-gear boxes with long lengths of shafting were used, but all gave trouble within a few hundred hours' flight. German rigid airships derived great benefit from the Maybach engine, which was developed at the same time as the ship's designs progressed, and was developed primarily for airship purposes. It departed from other aeroplane practice in many respects, and though it was not till quite late in the same that a modified type of a Maybach was used in aeroplanes, the German industry gained the experience of the development. In the British airships constructed during the war there was no intermediate shafting, the airship being mounted on the engine.
AEROPLANE
AEROOTHERAPEUTICS

In some cases a reduction gear was incorporated in the engine. In the first ships of the N.S. class a length of shafting was used in order to give a better shape to the engine car and obtain better air-streams. This was partly due to the theory of the reduction gear, but account of torsional resonance, and the airscrews mounted direct on the engine. In the German rigid airships, however, where more weight was available, the reduction gear box and intermediate shafting were made of steel, with only one airscrew mounted direct on the engine. Pre-war British airships and the first few rigid were fitted with swivelling propellers. The airscrews were carried at the ends of horizontal arms and driven through bevel gearing so that the axis of the airscrew could be rotated about its own axis, and the direction of thrust of the airscrew changed from ahead to astern, up or down. The ability to exert a vertical force independent of the bow of the ship was a great advantage to the then comparatively inexperienced pilots under the heavy landing facilities then existing.

Though engine failure has not the same consequences in an aeroplane, the machinery must still be regarded as the part of the airship most frequently in need of overhaul. Experience shows that the engine cars must be easily detachable so that spare cars can be fitted and thorough overhaul made possible without excessive delay to the ship. They must be as the locomotive to the train, not as the machinery to a battleship.

Hydrogen as Fuel and Recovery of Excess Water as Ballast.—During the final days of the war, the German government decided to employ hydrogen as a fuel in order to give her submarines a greater speed and range. Hydrogen produces steam equivalent to almost 1 0% of its weight, and the proportion of this which can be collected depends upon the temperature and humidity of the issuing gas. The chief difficulty in the collection of condensation is due to the cooling of the cooling surfaces with an open oil depot.

Attempts have been made to burn, as supplementary fuel, the hydrogen that otherwise would be discharged. When burning hydrogen alone in an engine with a compression ratio of about 5:1 it is not possible to develop more than 25% of the engine's full power without serious detonation. When petrol and hydrogen are burnt together, however, the mixture can be so adjusted that any amount up to full power can be developed. A few of the smaller airships were fitted in this way but the system was abandoned on account of increased risk of fire.

Risks of Fire.—Apart from hostile incendiary action the risk of fire in the air is small and is mainly due to the petrol. It is thought that the use of heavy oil fuel would give added safety. The heavy oil engine at present involves prohibitive weight, but a Diesel engine would be lighter and capable of burning only .5% of fuel per h.p. hour would, on the basis of 100 hrs. flight, justify an increase of machinery weight of 12 lb. per h.p. over the 5 lb. per h.p. of the petrol machinery with 100% h.p. hour.

Winches (for Kite-Balloons).—The earliest form of winch used had a steam engine driving a single drum on which the wire was wound. It was mounted on a single chassis and was drawn by horses.

In 1915 the French adopted a steam winch of Col. Renard's design which was fitted with surge drums—a pair of drums round which the cable makes a number of turns in grooves of correctly formed section. These drums transmitted the whole of the engine or brake torque to the cable and allowed it to be stowed on a separate storage drum under comparatively small tension and, therefore, less subject to damage. The steam winch as used by Armstrong Whitworth engineers, where the drums, liquid brake and storage drums, was adopted, with only modifications in detail, as the standard for all future winches.

The later winches were usually driven by petrol engines independent of the motors driving the cable drum. This was the most convenient forms of power available.

Gas for Airship Purposes.—Hydrogen is almost invariably employed for airships and balloons. Coal gas is cheaper and more universally available but is practically non-flammable. Sometimes ballast is carried with a lifting power of only about half that of hydrogen. Helium, although having only 93% of the lifting power of hydrogen of equal purity, is totally non-flammable and has, therefore, signal advantage in this respect. Helium is not an element, but is a rare gas, occurring in traces in the atmosphere and the oceans.

Variation of Lift.—The total upward force on the airship when at rest is termed her "gross lift." If V be the volume of gas in the ship, ρ its density and ρ the density of the surrounding air: Lift = V(ρgρ).

Variation with Height.—The lift is constant as the ship ascends until a height "term"—the pressure height—is reached at which the gas spaces have become full and further ascent causes an actual loss of lift. When descending, the lift will similarly remain constant, because V varies directly and ρ and ρg inversely as the height, assuming that the temperature of gas and air remain equal. As the ship rises above pressure height, V remains constant but ρ and ρg decrease.

Variation with Barometer.—nil until the ship becomes full; after that it varies directly with the barometric reading.

Variation with Temperature.—Provided the temperature of the gas remains the same, the following formulae are applicable: the lift of the ship will decrease inversely as the absolute temperature rises. Cylindrical heat falling on the ship raises the gas temperature somewhat, as much as 4°F. and often 20°F. above that of the air. The gas temperature changes comparatively slowly as the ship moves through air of varying temperature, hence there may be a considerable difference between the gas and air temperatures and this will substantially influence the lift of the airship.

Variation with Gas Purity.—The composition of the gas affects the lift of the ship. Hydrogen, being lighter than air, will lift nearly twice as much as coal gas. The lift of air is nearly twice that of hydrogen.

AEROTHERAPEUTICS: see AERONAUTICS.

AEROTHERAPEUTICS.—The term "aerotherapeutics," as a special branch of medicine, might convey the idea that there are special diseases due to aviation which require special treatment.
But such is not the case, as there is no special "flying sickness" brought about solely by the pursuit of aeronautics. Although certain authorities have inclined to recognize some mechanical effects owing directly to the reduction of atmospheric pressure upon the body, this is only of importance in connexion with the air enclosed within the cavity of the middle ear and to a lesser extent as regards gas inside the intestines. Changes of absolute pressure of the atmospheric produce mechanical effects since the altered pressure is transmitted equally in all directions through the semi-fluid body tissues. The suggestion has also been made that, owing to the diminution of atmospheric pressure, the airman may be liable to a special disease, somewhat akin to that experienced by the diver or the worker in compressed air. The cause of "diver's palsy," "caisson disease," or "compressed-air illness" is now thoroughly well established. When man is subjected to an increased air pressure he dissolves in the fluid portion of his blood a considerable amount of nitrogen from the surrounding air. When the air pressure is diminished, this nitrogen is again given off. If the diminution in pressure be rapid, then bubbles of gas are liberated inside the blood vessels, in the same way as bubbles of gas are liberated when fluid is removed from a siphon of aerated water. These bubbles then circulate in the blood and produce symptoms, according as they become lodged in the various parts of the body.

At first sight, therefore, it might be supposed that an airman making an ascent, in other words subjecting himself fairly rapidly to a diminution of the surrounding air pressure, might be liable to symptoms arising from the same cause as does "diver's palsy." This, however, is not the case, since the diminution in pressure is not sufficiently great or rapid to bring about any liberation of gases held in the blood plasma. In "diver's palsy" and "caisson disease" one is dealing with a reduction of pressure of from two to five atmospheres, whereas in flying one is generally dealing at most with a diminution of pressure of a little more than an atmosphere, which is reached relatively slowly, and is easily within the margin of safety for the rate of decompression in compressed-air work. The idea, therefore, that airmen are subject to any special "flying sickness" of this nature may be dismissed.

Because it is stated that there is no "flying sickness" it does not mean, however, that flying may not cause bodily breakdown. Flying imposes a very definite stress upon the body, especially when flights are carried out for long periods at high altitudes. When to this is added the stress of offensive and defensive warfare in the air it is obvious that bodily breakdown as the result of "strain" is likely to ensue. But the signs and symptoms of "flying strain" are varied and might occur in an individual quite apart altogether from flying. In the World War it was found that "flying strain" was most generally characterized by a gradual loss of power to fly high, associated in varying degrees with symptoms of respiratory, cardiac and nervous derangement, such as breathlessness on exertion, quickened heart-beat, exaggerated reflexes, marked tremor of fingers and eyelids, and loss of neuromuscular control as exemplified by power to balance on one leg. Mental symptoms, generally in the form of anxiety neurosis, might or might not be present. In many cases it was difficult to say whether breakdown was to be attributed primarily to the effects of flying or to the nervous strain of aerial warfare, but such symptoms were frequently found to occur in those who had taken no part in active service in the air.

In order to appreciate the correct medical measures which must be taken in respect of the care of flying personnel, it is necessary in the first place to consider the human machine in relation to flying. The aviator provides the controlling and coördinating mechanism on which the satisfactory performance of the aeroplane depends. The pilot adds the aeroplane to himself—the "Joy-stick," engine controls and so forth are appendages to his hands, the rudder bar an extension to his feet. By appropriate movements of his upper and lower limbs man is now able to fly, just as previously by appropriate arm and leg movements he was able to indulge in games or to control other forms of mechanism, as, for example, a motor-car.

To acquire the art of flight, therefore, a number of controlled and coördinated movements are necessary. It is common experience that certain people are found heavy-handed or heavy-footed and not likely to acquire the art of flying. In the apt pupil these coördinated movements are at first all made as the result of conscious effort, but later they pass into the realm of the automatic, so that eventually the expert pilot does not have to think how he flies—he just wishes his machine to perform a certain evolution and it occurs.

No elements come into the mechanical problem of flying that are not required for driving a motor-car or taking part in various sports; some men have more aptitude for flying than others, just as some have more aptitude for games.

To initiate the coördinated movements necessary for flying, the pilot relies upon certain sensory impressions. Vision is the most important. Without facilities for using his eyes a man is not able to fly. It has been found that experienced pilots cannot satisfactorily perform even a simple evolution with the eyes blindfolded. It is also well known that pilots cannot fly level in fog and may even get upside down. This is due to the temporary eclipse of the sense of vision; unaided by instruments, man will never be able to fly in a fog successfully.

Besides good visual acuity it has been found that harmonious working of the muscles moving the eyeballs is necessary, particularly for successful landing, and is lacking in a great percentage of bad landers. By careful training it has been found possible to bring about good visual judgment of distance and to turn bad landers into good ones.

For successful flying, next to vision and perhaps almost equally important, come the sensations from the skin and muscles. A pilot flies very largely by the "feel" of his machine. In addition to the "feel" of the controls, he derives much information from the "feel" of his seat, from the direction and change of direction of the wind on his face. He is also aided by hearing the singing of the wind in the wires. Hearing is of importance also in flying in so far as it enables a pilot to detect a failing engine, to operate wireless and to hear a telephone above the roar of the engine.

According to some people it has been thought very necessary that a man should have a good sense of balance, but experience has shown, as already mentioned, that "balance sense" is not sufficiently developed in any man to enable him to fly level in a fog.

But for flying it is not sufficient to be endowed with a mechanical and mental aptitude; a consideration of prime importance is physical endurance to resist the stress of high flights or flights of long duration. For endurance it is particularly important that a man be fit as regards his respiratory and circulatory mechanisms. This has been shown by the examination of fit pilots as well as of subjects who have been deemed in need of a rest or who have broken down as the result of flying strain.

The examination of successful flying officers showed that they were possessed of an efficient respiratory capacity. The examination of officers taken off flying through "flying strain" showed that their capacity was very much diminished. It was found by careful observation that this fall was due chiefly to ineffective working of the "exhaust" or respiratory side of the respiratory "bellows." The individual had lost his power to expire fully to the greatest extent. He, therefore, could not empty his lungs satisfactorily. Such a condition makes for deficient ventilation and the subject becomes very like a motor-engine in which the exhaust valves are defective and incomplete scavenging of the cylinders results. Hence we find that the airman in this condition easily gets breathless on the ground and certainly cannot fly to heights at which formerly he did not notice anything abnormal in his breathing.

For endurance and high flying, therefore, it is especially important that a flier have an adequate "bellows capacity" and that the "bellows" be particularly effective on the exhaust side. An efficient respiratory force is, therefore, very necessary to the pilot.

Examination of successful flying officers also showed that the effective pilot is possessed of an efficient circulatory system.
Observation has shown that there is a marked difference between the fit and unfit pilot in this respect. For example, the fit pilot is possessed of a regular, fairly slow pulse which gives the impression of a delightfully easy-working piece of mechanism. It is not greatly quickened by exercise and speedily returns to its normal rate. The pulse of the man unfit for flying, or unfit to learn to fly, is unduly quickened by exercise and takes considerable time to return to normal.

Circulatory efficiency also depends upon the pressure maintained in the arteries both during and between the beats of the heart. With the beat of the heart the pressure in the arteries rises: during the rest period it falls. In some people it may fall greatly, in others but a little. The examination of successful flying officers has shown that in them the fall is not great, whereas in the tired or inefficient individual the difference in the pressure during and between the beats is relatively large. The importance of a good pressure between the beats will be appreciated when it is realized that if the fall of pressure be great enough,ainting may result.

The efficiency of the circulatory mechanism of the body is intimately bound up with the efficiency of the respiratory mechanism. The abdominal cavity has sufficient vessel capacity to take the whole of the blood of the body and, in the upright or sitting posture, blood, by virtue of the effect of gravity, will tend to stagnate there unless its return to the heart is aided by the movements of respiration. In inspiration the downward thrust of the great muscle separating the chest from the abdomen, the diaphragm, acts like the piston of a pump and squeezes blood upwards into the heart, since it is prevented from escape in any other direction by means of valves placed in the vessels. During expiration the muscles of the abdominal wall and of the lower ribs squeeze inwards upon the abdominal contents and again force blood upwards to the heart.

The importance of these accessory pumps to the circulation is well exemplified in the crucifixion of a man. In the vertical posture the immobilization of the limbs and the restriction of the action of the respiratory and abdominal muscles cause blood to stagnate in the lower limbs and the abdomen, thereby contributing the principal cause of death.

Since in the machine the pilot is rendered relatively immobile in a sitting posture, it is of the greatest importance that he be possessed of efficient respiration and good abdominal tone, in order that an adequate circulation may be maintained. The importance of good abdominal tone is further emphasized by the following experiment. If a hutch rabbit, with its flabby, pendulous abdomen, be held in the vertical posture, it will soon become unconscious owing to the lack of tone of its abdominal wall; a wild rabbit, on the other hand, will not do so, owing to the fact that, on account of the exercise taken in its free open-air life, it has developed the tone of its abdominal musculature.

This emphasizes the value of sport in developing the respiratory and circulatory mechanisms, and for this reason all airmen are advised to take up sports which, besides giving eye and limb coördination, also give physical endurance, by toning up the respiratory and circulatory mechanisms. The importance of sports and games in the life of the flying man cannot be over-emphasized.

In addition to the power of endurance the pilot must also be possessed of quick perception and judgment, which, besides enabling him to learn to fly, will help him to meet any sudden emergency which may arise while he is in charge of his machine in the air. He must therefore possess good mental and nervous stability. Such stability is of even greater importance in the service pilot who may be called upon to undertake combatant service in the air.

Since 1878 it has been known that the chief cause of "mountain sickness" or "altitude sickness" is lack of proper oxygenation of the body owing to the rarefaction of the air breathed. Experiments conducted in rarefation chambers as well as at high altitudes, such as Pike's Peak and Monte Rosa, have fully proved this point. In respect of life at high altitudes, however, a certain degree of bodily acclimatization takes place, which is not the case in respect of flying. In an aeroplane the length of sojourn at high altitudes is insufficient to induce any acclimatization, beyond possibly a transitory concentration of the blood plasma. In flying the effect of increasing altitude is in the first place a deepening of the respiration in order to secure the oxygen necessary to maintain the bodily functions. At the same time the heart quickens, and thus is established the beginning of a "vicious circle." For an increase in the rate of the heart-beat means an increase in the amount of work done by the heart, and this increased work entails an increased oxygen consumption, the supply of which is diminishing; thus each factor reacts unfavourably upon the other.

All the devices to render the respiration and circulation efficient will, therefore, be called into play to meet the changing conditions, so that with prolonged and repeated stress a breakdown of the respiratory and circulatory mechanisms, involving also the nervous system, is to be anticipated, unless appropriate measures are taken to mitigate the ill effects. This has been found to be the case.

The effects of flying at great altitudes were observed as the result of the high flying which became necessary during the World War. In the earlier stages of the war such flying was the exception rather than the rule. Owing to the increasing altitudes reached by aeroplanes, however, it became eventually quite an ordinary event for high-flying aeroplanes to maintain an altitude of from 20,000 to 22,000 ft. for several hours. When this first took place it was found that after a time the pilots and observers began to suffer from the effects of prolonged exposure to such altitudes. In the air the chief among these effects were breathlessness, muscular weakness and diminution of judgment followed by great bodily fatigue. This, when frequently repeated, led to the signs of breakdown already given.

Another effect of high altitudes was the onset of drowsiness or sleepiness. In some cases this was excessive and pilots have stated that they have fainted at great heights and cannot remember landing, whereas they have actually been sufficiently awake to fly the machine and land it in their own aerodrome with verbal assistance from the observer.

At great altitudes there is, therefore, either a general slackening of moral and loss of offensive spirit or else a feebleness of judgment which may lead a pilot into unnecessary difficulties. The effects of high altitudes upon judgment are insidious and constitute for the aviator a subtle danger.

Some flying officers eventually complained of headaches which at times came on while in the air, but more usually after landing. Vomiting and bleeding from the nose were very rare indeed. Cases of syncope were infrequent.

As with "mountain sickness," the symptoms described above are chiefly due to oxygen want and it was found that with the provision of oxygen apparatus on high-flying machines these symptoms were greatly alleviated.

As is well known it has been shown that the administration of oxygen (1) tends to keep an efficient slow pulse; (2) tends to keep up a good arterial pressure; (3) keeps off the onset of distressful breathing; (4) mitigates any ill effect due to excessive deep breathing; (5) increases the power for nervous concentration and muscular work.

In flying, particularly in high flying, it is important that the pilot be able to accommodate himself to the effects of diminished pressure upon the air enclosed within the middle ear and the air passages connected with the nose. Any hindrance, for example, to effective ventilation and drainage of the frontal sinuses in the brow may lead to headaches of varying duration. As regards the ear, the external orifice affords a wide passage by which alterations of air pressure are easily transmitted to the ear drum; on the other hand the Eustachian tubes, leading from the throat to the middle ear, are narrow passages which normally open only during the act of swallowing, and therefore do not so readily transmit changes of pressure. Any catarrhal condition or congestion of these tubes, therefore, tends to produce difficulty in the equalization of pressure within and without the tympanic cavity. Generally speaking, during an ascent the ears are
unconsciously "cleared" by swallowing, which under ordinary circumstances is sufficient to open the Eustachian tubes and equalize the pressure on both sides of the ear drum. Occasionally a very graduated self-inflation, just sufficient to open the tubes, may be required to dispel a sensation of fullness in the ears. If, however, owing to very marked obstruction of the Eustachian tubes, no equalization of pressure has taken place, then at 20,000 ft. the pressure in the external auditory meatus is approximately 380 mm., while in the middle ear it is still 760 mm. (ground level), a difference of 380 mm. tending to push the drum outwards. If, on the other hand, during the relatively slow ascent to this height equalization of pressure is made, but, owing to Eustachian obstruction, little or no equalization is made during a rapid descent, then on reaching ground level there is through the external ear a pressure of 760 mm. but only about 380 mm. in the middle ear, to which pressure the drum painfully resists. Such an "invagination" of the drum is sometimes found immediately after landing in pilots who complain of deafness, discomfort or pain in the ears, headaches, dizziness, nausea and, in certain cases, vomiting and fainting in the air. In less severe cases, inspection of the ear drums often shows marked distension of the blood vessels. On enquiry it is usually ascertained that the symptoms complained of have come on during descent or immediately after landing, and are in many cases attributable to difficulty in equalizing the pressure within and without the tympanic cavity. It has been found also that one-sided obstruction of the Eustachian tubes may cause vertigo and incoordination in the air. The importance to the aviator, therefore, of adequate ventilation and drainage of the middle ear through the Eustachian tubes under rapidly varying degrees of atmospheric pressure is manifest. Broadly speaking, any condition of the nose or throat which causes or is likely to cause post-nasal or pharyngeal catarrh is a potential factor in the causation of Eustachian obstruction. Abnormal conditions of the nose, throat and ears which are apparently of trifling importance on the ground tend to become considerably aggravated in the air. Free nasal respiration and a healthy condition of the upper respiratory tract are therefore necessary in the aviator.

From what has been written it will be seen that the medical measures to be taken as regards flying consist in (a) the careful selection of flying personnel; (b) the effective care of those selected.

In the main the case for careful selection has been presented. The great necessity of nervous stability, efficient respiration and circulation has been shown. Attention has also been directed to the important part played by vision, as well as to the necessity of a healthy state of the ears and upper air passages.

A word may be added here as to the importance of vestibular state. It is likely that pilots who have experienced a "flying blind" in a fog, in certain countries, particularly in the United States, great importance was at first attached to the supposed "motion-sensing functions" of the vestibular apparatus. On them the success or failure of candidates for flying was believed largely to depend. The sensitivity of the vestibular apparatus was tested by means of "rotation tests." As the result of special investigation, so great an importance is not assigned to these tests in England. Generally speaking, rotation tests therefore are only employed when a candidate gives a history of giddiness, train or swinging sickness, suggestive of undue sensitivity of the vestibular apparatus.

At first no special medical examination was made for flying, but early in the World War medical officers with squadrons collected considerable evidence which proved that a special examination was necessary. They were constantly seeing pilots who were breaking down or had actually broken down from causes which should have precluded their admittance to the flying services.

In addition to visual defects, otitis media, and conditions resulting in Eustachian obstruction, numerous instances of gross nervous instability were observed amongst unfit flying officers, who could never have been accepted for the service had details of their past histories been elicited at a medical examination.

In the selection of flying personnel the importance of the past history of the candidate cannot be overestimated.

Nowadays candidates in England, both for military and civil aviation, are submitted to:

1. A surgical examination, comprising, in addition to measurement of height and weight, observations as to any existing surgical abnormality, congenital or the result of injury or disease, which is likely to impair the efficiency of the individual.

2. A medical examination, including enquiries as to previous occupation, family and personal medical history, an investigation of the various systems, including special tests for flying efficiency.

3. An examination of the eyes from the point of view of normal acuity of vision and also of good ocular muscle balance. Normal colour vision is also demanded.

4. An examination of the ears, nose, throat and buccal cavity, including tests of hearing, the patency of Eustachian tubes, and, where necessary, a test of the sensitivity of the labyrinthine apparatus.

5. An assessment in which, after such further examination as appears necessary, a decision is formed as to the candidate's fitness for flying.

The special tests employed in the assessment of efficiency are as follow:

For respiratory efficiency:

1. Measurement of the respiratory capacity by means of a spirometer.

2. The length of time during which the breath can be held after full expiration and full inspiration.

3. Measurement of the expiratory force—that is, the height to which the subject can force a column of mercury with the cheeks and lips held.

For circulatory efficiency:

4. The pulse rate sitting, standing and after regulated exercise (lifting the body weight on and off a chair five times in fifteen seconds).

5. Measurement of the systolic and diastolic arterial pressures.

For nervous stability and neuromuscular coordination:

6. Observation of knee jerks and other reflexes.

7. Observation of presence or absence of tremor of eyelids, tongue and fingers.

8. The ability of the subject to stand steadily on one leg for 15 seconds with the eyes closed and hands to side.

9. The ability of the subject to raise from table to shoulder level and replace again an unstable rod placed on a piece of board.

Tests for endurance and resolution (testing respiratory and circulatory efficiency and nervous stability):

10. After full expiration and full inspiration, the length of time during which the subject can support with the breath held, a column of mercury at 40 mm., the rate of the pulse being counted meanwhile.

The standards for these tests, which are used as adjuncts to the clinical examination, have been set by the examination of deficient pilots who have rendered satisfactory aerial service. Results have also been obtained from larger numbers of pilots who have partially or wholly broken down.

The duty of forming a final decision as to the candidate's fitness for air work rests with the assessor, a medical officer of wide experience. His decision is based upon a review of all the facts and observations recorded by the examiners, checked and supplemented by an examination on his part of such points as appear doubtful.

Apart from the elimination of cases which fail to satisfy the requirements in respect of the special senses of sight and hearing or show signs of organic disease of a gross or potentially disabling nature, the assessor's main duty is to ensure that the accepted candidate is possessed of a mental aptitude and a degree of stamina and nervous stability adequate to withstand the stress of training and of subsequent service in the air.

In forming an opinion on these points, no attempt is made to determine the temperamentality suitability of candidates by elaborate psychological methods. In most cases the assessor is able to gain an insight into the candidate's general "mental make-up" by interrogation as to his motives for wishing to fly, by ascertaining his keenness for sports and games and by obtaining details as to his service, if any, in the war. The evidence as to the soundness of the stock from which the candidate
comes, the illnesses from which he has suffered, the stresses to which he has been exposed and the manner in which they have been borne, are of prognostic importance. Reliable impressions are also formed in many cases in the course of ordinary clinical examination, additional aid in arriving at a decision being afforded by the candidate's method of performing the various tests of the cardiovascular, respiratory and neuromuscular systems. When deemed necessary the psychomotor reflexes may be measured.

After admission much devolves upon the medical officer in the way of careful supervision. As in other branches of the medical profession, the success of the medical officer in preventing breakdown from flying strain depends largely upon his mental aptitude for, and his attitude towards, his work. To the medical officer the flying officers under his care are so many human engines, and it is his duty to keep them as far as possible in fit condition, properly attuned, and to overhaul them periodically so that he can say whether they are wearing well or showing signs of strain, and, if the latter, to take necessary measures to prevent and, if necessary, to remove them.

The medical officer should live as much as possible among the officers under his charge; by this means he acquires an intimate knowledge of their characters, which he may use sympathetically and confidentially as occasion arises. Each flying officer is, so to speak, an individual unit, and requires his own special study. Much of the medical officer's best work, therefore, is done in the mess, on the aerodrome, or at games. For example, indications of "fatigue" may be observed when a pilot, usually efficient, begins to look bad, or returns from a relatively simple flight unduly exhausted; when a moderate drinker begins to take more than is good for him; or when a sociable pilot prefers always to sit alone quietly reading in the corner. A little tact and sympathy on the part of the medical officer under such conditions may make all the difference between recovery and breakdown.

It should always be borne in mind that a certain number of pilots are liable to develop an "anxiety" in regard to their occupation, especially as the result of the stress of early training or of prolonged service in the air. The first symptoms of such anxiety are best detected by a medical officer knowing each of his pilots personally. Thus during the training stage much information can be gleaned by a quiet chat with an officer or cadet in regard to his sensations while in the air, either when receiving dual instruction or when learning to acquire proficiency at aeroacrobatics. The stress of the first solo flight must always be borne in mind. It must be remembered also that a young officer is generally averse to showing any sign of what he fears may be deemed cowardice. Yet, during the stages of training, he is probably constantly repressing a tendency to be afraid, which is only natural. With such an individual a frank discussion of his fear with the medical officer will frequently improve his condition. It is a great help, from the pilot's point of view, to be assured by a medical officer in whom he has confidence that he is in good condition, or that he is not a coward, and that many other pilots who have eventually "made good" have been through the same stages of "wind-up." In gleaning information as to the "anxiety state," note should be made of such points as change of habits, restlessness, irritability, tendency to jump at any sudden noise, or inability to concentrate. Enquiry should be made as to the "anxiety state," note should be made of such points as change of habits, restlessness, irritability, tendency to jump at any sudden noise, or inability to concentrate. Enquiry should be made as to the "anxiety state," note should be made of such points as change of habits, restlessness, irritability, tendency to jump at any sudden noise, or inability to concentrate. Enquiry should be made as to the "anxiety state," note should be made of such points as change of habits, restlessness, irritability, tendency to jump at any sudden noise, or inability to concentrate. Enquiry should be made as to the "anxiety state," note should be made of such points as change of habits, restlessness, irritability, tendency to jump at any sudden noise, or inability to concentrate. Enquiry should be made as to the "anxiety state," note should be made of such points as change of habits, restlessness, irritability, tendency to jump at any sudden noise, or inability to concentrate.

Medical examination will also give indication of the onset of flying strain or fatigue, and if found, appropriate steps can be taken to prevent or mitigate it.

Attention has already been drawn to the great importance of the use of oxygen for flights at high altitudes or of long duration, as well as to the great value of sports and games in promoting flying skill and bodily endurance in pilots. Periodic advice by medical officers in respect of the ill effects of too much smoking or alcohol also play a part in the effective care of flying personnel. Advice may also be given in regard to the efficient protection of the body.

The intensity of the cold varies with the season of the year and with the height attained; it is accentuated also by the speed of the machine through the air. To prevent loss of body heat while flying, special suits have been designed, the cardinal principle of which is to keep the body surrounded by layers of warm air. In most cases this warmth is derived from the body, but the warming of clothing by electric means has also been tried. For warmth purposes, great thickness of clothing is by no means necessary. Underclothing should be loose-fitting; two thin garments of closely-woven texture, either of wool or silk, are better than one thick one. Research has shown that the warmth-giving power of clothing lies in the fineness of the mesh rather than in its thickness. Care should be taken to avoid orifices through which the outside air can permeate. Tight clothing should be avoided, particularly clothing which tends to hamper movements of the chest and abdomen or to restrict the circulation of the limbs. Frequently, however, it is necessary to employ considerable additional protection for the legs, especially for the feet, and for this reason care should be taken to provide suitable additional protection in the form of warm, loose-fitting stockings.

For the protection of the face, a fairly close-fitting head and face piece of non-absorbent and non-porous material may be made, the inner surface of which will not absorb the oil or grease with which it is advisable to anoint the face when severe cold has to be endured. Over such, a woolen balaklava may be worn, and then a flying cap of close-fitting design.

For the protection of the hands a series of suitable gloves may be employed; for instance, thin silk gloves covered by woolen gloves, the whole enclosed in a leather gauntlet, which can be easily removed for delicate work. Gauntlets provided with a specially adaptable finger muff are to be recommended. In certain cases electrically heated gloves have also been employed.

For the protection of the eyes well-fitting fur-lined triplex goggies should be employed. The fogging of goggies may be prevented by certain preparations which are on the market. Some pilots prefer to employ tinted goggles; this is especially necessary for flying in the tropics, otherwise the effects of glare are soon felt.

In regard to diet, gas-producing foods are best avoided, since altitude causes expansion of the gases of the intestines, but in practice there is little need for the healthy person to worry about the constitution of his diet. It is important, however, that no flying should, under any circumstances, take place upon an empty stomach.

Before long flights it is advisable not to partake of food of too fluid a nature or of too much liquid. By this means the desire to urinate in the air during a flight is avoided. On very long flights, a supply of liquid food, such as sweetened cocoa or malted milk, may be carried in special thermos flasks. In addition compressed food in the form of tablets or chocolate may be provided.

Finally if "flying strain" supervenes the treatment necessary is such as would be applied to the condition of "fatigue" arising in any other occupation. According to his chief symptoms the patient may pass for treatment of an anxiety neurosis to the neurologist or for the treatment of respiratory and circulatory symptoms to the general physician. But it is always to be remembered that the keynote of the effective care of flying personnel lies in prevention rather than cure.

AFGHANISTAN (see 1,306).—The visit of the Amir Habibulla Khan to India at the beginning of 1907 was destined to exercise a powerful and beneficial influence on the attitude of the Afghan ruler during the rest of his reign throughout periods of unusual crisis and strain. It gave him the opportunity of making acquaintance with British officials and Anglo-Indian society, and the result was a new development of friendship and mutual
confidence. The effect in Afghanistan of the Anglo-Russian Convention signed on Aug. 31 of the same year was not of a similarly happy nature. Articles III, and IV. of the Convention, which provided respectively for the establishment of direct relations between Russian and Afghan frontier authorities and the maintenance of equality of commercial opportunity for British and Afghan traders, were interpreted by the Afghans as an attempt to interfere with the economic autonomy and political independence of their country. Article V. laid down that the Convention would only come into force on the notification of the Amir's consent to its terms. This consent, though repeatedly pressed for, was never given by the Amir.

From 1908 to 1914 the history of Afghanistan remained peaceful and uneventful, and was chiefly remarkable for the gradual introduction into the country of measures of civil, economic and military reform.

Influenced by what he observed in India, steps were taken by the Amir to open schools, increase facilities for the education of the upper classes, establish factories, introduce telegraphs and telephones and to provide medical relief. The provision of improved medical and educational reforms in the training of the armed forces, wise taken in hand. For the above purposes a number of foreigners were imported into Afghanistan, and of these the majority were Turks. It was, however, in the direction of public works that the Amir showed to the maximum extent his appreciation of modern ideas. Great efforts were made by means of forced labour, to improve the internal communications. Metalled roads were constructed between the principal local centres, and in those districts which had not previously been fit for wheeled traffic, were brought into use. Roads were opened between Kabul and from Kabul to Dakka and from Kabul to Kandahar. Important irrigation works were also constructed, notably the Nahr-i-Siraj from the Helmand river near Kala Bist; from the Kabul river near Duranta; and the Panjshir Argandab canal from the Argandab river near Kandahar.

The outbreak of war in 1914 between Italy and Turkey created, as might be expected, a general wave of sympathy among the Afghans for the Turks. To counteract this sentiment the Amir, in his own interest, felt that it was necessary to undertake certain large-scale military developments, already one of the Amir's original plans, but which might have led to far different results had not the Amir Habbulla Khan, faithful to his pledge, maintained throughout the long years of the war an attitude of strict and correct neutrality and enforced it upon his country, notwithstanding many temptations and inducements both from within and without his country. Within Afghanistan the voice of religious bigotry and fanaticism was loudly raised on the side of Turkey, while the opportunities proclaimed against the folly of not taking advantage of so favourable a moment for successful aggression.

More seductive still were temptations from outside. Chief among these were the persuasions of an important mission which the German Government despatched towards Afghanistan in the spring of 1914. The party were selected to comprise such elements as would have the best chance to appeal to Afghan sentiment. Indian seditionists, were, both Mohammedan and Hindu, together with German and Turkish officers. The mission bore letters from the German chancellery, and were charged to make important revelations regarding possible future actions of the British and the German Governments in Afghanistan, Germany, Austria and Turkey. The mission reached Kabul through Persia towards the end of 1915, and were dismissed in May 1916, without effecting their purpose.

The continuous and unwavering loyalty of Amir Habbulla Khan to his pledges to the British Government throughout the changing vicissitudes of the World War forms one of the most remarkable in- clinations of the Amir's character. He not only maintained throughout the strictest neutrality of his country but has successfully influenced to preserve peace among the unruly tribes on the frontier, thereby diminishing demands on the depleted garrison of India.

With the Armistice of Nov. 1918 the War came to an end, but Afghanistan was not long to enjoy the benefit of peace. At 3 A.M. on Feb. 20 1919 Amir Habbulla Khan was shot in his bed in his tent at Kalâ Gosh while touring in the district of Lamaghan. His brother Nasrulla Khan, then at Jalalabad, at once proclaimed himself Amir of Afghanistan in his stead. Prince Amanulla Khan, the third son of the late Amir by his principal wife, the Ulya Hazrat, who was then residing at Kabul as governess, was proclaimed Amir. Amir Nasrulla Khan, the son of the deceased Amir, was proclaimed Amir of the tribe of the people of all classes at the capital. His uncle Nasrulla Khan at once declared in his favour, and his elder brothers, Inayatulla Khan and Hayatulla Khan, and other members of the royal family, acknowledged his succession to the throne. The facts relating to the murder of Habbulla Khan have never been made known. Nasrulla Khan was charged with complicity and sentenced to imprisonment for life. In a letter dated March 3 1919 to the Government of India, Amanulla Khan announced his accession with protestations of friendship to the British Government. Mischievous and unfounded reports of rebellions in India and of British tyranny in India and Mesopotamia were spread broadcast by official agency throughout the country and frontier tribes, and exhortation was addressed to all to be prepared for a call to arms. This was quickly followed by an armistimation of 31 days (holy war) and the captivity of the credulous Afghan people and frontier tribes was aroused by promise of an easy conquest of India.

Early in May information accumulated to the effect that the plan of operations decided upon by the Afghan Government was to attack simultaneously on three fronts under separate generals through Dukka, Khost and Baluchistan, by boyds of Ghazi (religious fanatics) supported by regular troops. Prompt measures were accordingly taken to reinforce British forces on the Indian frontier. The arrival of Afghan troops at the western end of the Khyber was immediately hailed as a hostile act by the occupying powers.

The occupation by Afghan regulars of the heights commanding Landi Kotal. From there they were immediately expelled, and the Amir's troops, to the number of 25,000, under the command of Amir Habbulla Khan, were ordered to advance on the Khyber. This plan of action was successful, and the arrival of these forces on May 25 was a most important factor in the capture of the Baldoch which threatened the security of the southern capital of Kandahar.

In a letter dated May 28 the Amir addressed the Viceroy of India, definitely asking for peace and suggesting a cessation of hostilities. He was informed in a reply dated June 2 that an armistice would be granted on certain terms, which included the withdrawal of all Afghan troops from within 20 m. of the British frontier and the exercise of the Amir's influence in restraining the frontier tribes from further hostilities. These terms were accepted by the Amir in a letter of June 11, in which he agreed to send delegates to India to discuss terms of peace and the reestablishment of former friendly relations between the Afghan and British Governments. These delegates duly arrived at Rawalpindi on the date appointed, July 25, and peace was formally signed on Aug. 8.
in the British line of defence or occupation. Instances of loyalty to the British Raj were, however, numerous. In the north the tribal levies received training, and occasionally served in continuous Afghan War, while in the Kurram and Swat valleys, and farther south in Baluchistan, all but a few tribes remained firm. Military operations throughout this period of struggle were of an exceptionally severe and arduous character, especially to the tribes living along the border of the season of the year in the frontier tracts, but to the severe outburst of cholera which occurred along the whole front and caused serious losses among the troops engaged. The armistice of June 11, which terminated the fighting between the rival armies, left little further to do, but left little effect on the guerrilla warfare raging along the frontier, and this continued, notably in Waziristan, until even after the signing of peace.

The treaty of peace laid down that the British Government, in view of the circumstances which led to the war, would on their part withdraw the privilege, hitherto enjoyed by former Amirs, of importing arms, ammunition and warlike stores at any time. The British Government could confiscate the arrears of the late Amir's subsidy and grant no subsidy to the present Amir, but would be prepared, if the Afghan Government gave proof, by good conduct in the meantime, of a genuine desire for friendship, to receive another Afghan mission after a period of six months, to discuss the settlement of matters of mutual interest and the reestablishment of friendly relations. The Afghan Government on their part agreed to adhere to the Indo-Afghan frontier accepted by the late Amir, and also to assent to the early restoration of the hitherto undemarcated portion of the line to the west of the Khyber; British troops were to remain in their present positions until the removal of the troops was accomplished.

Demarcation was satisfactorily completed and British troops accordingly evacuated Dacka on Sept. 13. The Afghan fort of Spin Balak had been previously evacuated on Aug. 14. In December, a treaty marked an important departure from previous practice in that no mention is made in it of the dependence of Afghanistan on the British Government in external relations, and to which Mr. Amirs, Adburrahman and Habibulla Khan, had bound themselves to follow the advice of that Government. In a letter handed by the Foreign Secretary to the Government of India to the Afghan delegate immediately after the signing of the treaty it was stated that the treaty left Afghanistan free and independent in its affairs both internal and external.

Reference has been made to the despatch in April 1919 of an Afghan mission to the Soviet Government at Moscow, under Wali Mohammed Khan, reached Moscow in Oct., and were well received. Meanwhile, in Sept. 1919, the Soviet Government of Turkestan despatched a mission to Kabul under M. Bravin, a former member of the Russian imperial consular service. In Nov. 1919 the Soviet Government of Moscow, desiring to establish a more direct control by themselves of foreign relations in Asia, sent a mission to the Amir of Afghanistan, which was received with the utmost cordiality by Mr. Suritz, superseding M. Bravin, at once commenced negotiations with the Afghan Government, and in the course of the summer despatched to Moscow the draft of a treaty which it is understood, provided for the establishment of Russian consular posts at Chagai, Quetta, and Jalalabad, and for expert instructors and the establishment of Russian consulates in both eastern and northern Afghanistan.

There was a lengthy correspondence between the Indian and Afghan Governments, which decided that an Afghan mission, as arranged in the treaty of peace of Aug. 8, 1919, should be sent to India. They arrived at Mussoorie on April 14, 1920, under the charge of Sardar Mahmud Beg Tarsi, the Afghan Foreign Minister, and were met by a British delegation under Sir Henry Dobbs, the Foreign Secretary to the Government of India. The conference lasted until July 24, when the Afghan delegation were presented with a statement of the general lines on which the British Government were prepared to discuss a formal treaty. Throughout this period the attitude of the Afghan Government in respect to questions under discussion was not only one of backwardness and by outside concurrent events, notably by the striking of a blow for the liberation of the Turkish Nationalist position in Anatolia, the change of Government and the growth of Bolshevistic influence in Persia, the outbreak of revolt in Mongolia, and the general agitation in China. Near home also, a renewed outbreak of hostilities, fostered and assisted by the Afghan agency, on the Indo-Afghan frontier in Waziristan, led to lengthy military operations, and raised hopes in the mind of the Amir that he might insist that the British Government should be disposed to consider the question of changes in favour of Afghan-

AFCRA (see 1320.—Territorial changes in Africa between 1910 and 1921 resulted in a repartition of large areas of the con-

1These figures are subject to rectification on the full working-out of the data obtained by the expedition.
forming the Nile-Rudolf watershed, which drops abruptly into the Tanganjika plain in the Rudolf side, but slope gradually west to the Nile. It has heights of 10,000 feet. The expeditions named nearly completed the exploration of the region between the Nile and Abyssinia. In 1915-16 Maj. Churcheer Christy made a ten-month journey through the central part of this region, which forms the frontier of the Anglo-Egyptian Sudan. The divide proved to be "a continuous and more or less level strip of bush-covered country (mostly of ironstone and sandstone), and of varying width, generally about one mile, but often only a few yards." In Maj. Christy's opinion the divide was perfectly suitable for the building of a railway, a roundabout link in the Cape-to-Cairo scheme.

In 1913-14 the Tanganjika railway was begun. In 1913-14 explored part of southern Jubaland. He reached the Lorion Swamp--which receives the waters of the Uaso Nyiro--and solved the problem of the valley. He found that the Lake Deriva issues from Lorion in a well-defined basin. It crosses the Tana river in its lower course. The Wama, a tributary of the Juba river. Mr. (afterwards Sir) G. F. Archer completed in April 1912, after over two years' work, surveys connecting the triangulation of British East Africa with Maj. Gwynn's Abyssinian boundary survey. Captain R. E. Salkeld in 1913-14 further explored Jubaland, drawing attention to the over-running of that region by the Somali--the most recent instance of the migration of African races.

In central east Africa a survey by Capt. E. M. Jack, in 1911, of the region N.E. of Lake Kivu and W. of Victoria Nyanza resulted in making known a healthy highland region and added to the knowledge of the lake and the basin of Lake Albert. It was found to be 14,780 ft. high. In Dec. 1912 Sir A. Sharpe and Mr. M. Elphinstone witnessed the formation of a new volcano, named Katah Мау, in Nigeria. In 1912 a Russian group, finding old lavas covered lava-field, sending into the N.E. corner of Kivu a river of lava which filled up a "large bay," the first survey along its whole length of the Congo-Zambezi waterway was made in 1914. In 1912-3 Portuguese boundary commissions, the principal commissioners being Capt. Everest (killed by a lion), Maj. E. A. Steel and Maj. Reginald Walker (British); Maj. Beugrad and Capt. W. E. B. and Capt. C. G. Cape Coutinho and V. da Larga (Portuguese). As in the Congo-Nile watershed, it was found that many rivers ran for considerable distances parallel to the divide, which is largely bush-covered. Major Wallvock was sent in 1912 to the Limupa, which runs parallel to the Tanganjika (the Congo did not, as was believed, issue from Lake Bangweulu, but was a continuation of the Chambesi, which passes through the great swamp S. of Bangweulu.

Another boundary commission, under Capt. W. V. Nugent and Oberleutnant Detzner, in 1912-3 demarcated the Nigeria-Cameroon frontier between Yola and the Cross river. The frontier followed roughly the edge of the highlands overlooking the fertile plains of the Benua and was an instance where the straight lines drawn on the map by diplomats to mark international boundaries worked out fairly well in practice.

The complications of campaigning led to many additions to exact knowledge of the topography of tropical Africa, partly through the use of aircraft for survey purposes. Thus very useful was the surveying work undertaken by the airship Whitehead. In 1912 the existence of some unknown Tertiary volcanic field in that region had been suspected. Exploration on the ground remained to be undertaken, but Dr. Chalmers Mitchell's observations would appear to be the first to show the discovery were coupled with the surveys, the first trench of the Indian Ocean to be made in 1918, inspected an area of the Andaman island, S. of the Natal coast. The plan was to construct a line of steamer from the Cape to Cairo, with only two breaks--together not more than 300 m.--to be covered on foot. The southern break was from Tabora (on the Tanganjika railway) to Mwanza, on Victoria Nyanza; the northern break was on the Nile at Rejal, along the banks of an un navigable stretch of the Upper Nile.

These cross-Africa routes were valueless for through goods traffic; their function was to bring the produce of Central Africa direct to the nearest seaport. Thus the Tanganjika railway made Dar es Salaam the natural outlet for the trade of a large portion of the eastern part of the Belgian Congo. With these main routes may be added the line (built, 1916-18) from Qantarra on the Canal, across the Sinai peninsula to Gaza, which put Africa and Asia in direct railway communication, Cairo being linked with Jerusalem, Damascus, Aleppo, etc.

In Africa by railway, from Algeria to the Niger countries, surveys made in 1912-3 showed that there were routes presenting no engineering difficulties. From Msala, in the Algerian Sahara, a railway route of the Congo-Lualaba-Mpimbwe line, to the Niger at Tosaye (Burem), some 200 m. below Timbuktu. What was regarded as the first section of the trans-Saharan was the line from Biskra to Tuggurt, opened in 1914. From Tuggurt to Tombouctoo, built in 1914-15, 1,470 miles. A line from Biskra to Jelfa, on the way to Laghaw, was also built.

French projects to connect the Middle Niger with the ports of the Guinea Coast were hindered by the World War. The scheme was for railways from Bobo (Senegal), from Farkaim (Senegal), from Abidjan (Ivory Coast) and from Doum (Dahomey) to be carried inland to the French Sudan (Upper Senegal and Niger colony), and there united by a transverse line. Political and economic considerations induced the French to connect the rail with the Nile at Sennar; the natural outlet for the French Sudan--the Gambia is navigable from the ocean by vessels drawing 15 ft. up to 135 m. inland. Of these proposals, the only one realized was a link of a few hundred m., Kureh, built in 1917, has a length of 682 m., of which about 100 m. remained to be built in 1920. The French Guinea line from Konakry reached the coast (305 m.) in 1910 and Kankan in the French Sudan, 411 m. from Konakry, in 1915. This led to much of the trade of the countries in the Niger bend going to Konakry. The Ivory Coast railway from Abidjan, traversing a dense forest region, reached Buaké (153 m.) in 1913. No progress northward had been made after 1912. The line was completed in 1912. All four lines are of the French standard West-African gauge, namely one metre. Besides the railways the French built a number of roads of mixed gauge, and also motor services connecting with the Niger countries were established.

In British West Africa local lines and extensions, ஆயிரத்தில் 1915-20; there was no unity of plan between the different systems. In 1917 N. of the Niger at Jebba, completed 1914, gave the chief Nigerian railway, that from Lagos to Kano (704 m.) long, an uninterrupted service. In 1913 a new railway was begun from Port Harcourt, at the mouth of the Bonny river. It was completed to the Udi coalfields (151 m.) by May 1916. From Zaria, on the Lagos-Kano railway, a branch line, built across the tifield area to Bukuru (143 m.), was completed in 1916. The surveys were made for an extension of the Port Harcourt-Udi line northward across the Benue river and thence north-west to a point, Kaduna, on the Lagos-Kano line. The building of this extension, some 450 m. in length, was in progress in 1921. These railways are coupled in connexion with the railways, which are Government owned.

In Morocco the French, from 1912 onward, built narrow-gauge railways for military purposes. By 1920 these connected (1) Salé near Rabat, (2) Upper and Lower Casablanca, (3) Marjeh from Rabat, (4) the section Fez-Taza was under construction. From Rabat via Casablanca another line was built to Marrakesh. The river dividing Salé and Rabat was not bridged, but a ferry service was maintained until 1918. The French planned to extend the lines to Meknes and Marrakesh on the normal gauge. Up to 1920 no progress had been made on the Tangier-Fez railway. In North-East Africa the decade 1912-21 saw the extension of the railway from Jibuti to Addis Ababa, the capital of Abyssinia.

The greatest mileage of railways built in the period under consideration was in South Africa (see SOUTH AFRICA). A line from Beira to Zambesi was begun in 1920, and the railroad was equipped with access to the ocean. The Germans provided their South-West Africa Protectorate with an extensive system of railways. In Uganda the British built a short railway linking Jinja, on Victoria Nyanza, with
the first navigable stretch of the Nile, and during the World War a line connecting the Uganda railway with the Usambara railway in German East Africa was constructed.

The telegraphic system was greatly extended between 1910 and 1920, while from the first-named year gaps in the telegraphic lines were increasingly filled by wireless telegraphy. The first wireless station (at Darfur) was opened in 1910. The Germans by the middle of 1914 had just completed powerful wireless stations in Togoland, South-West and East Africa. The French built stations in West and North Africa (Dakar, Algiers, etc.) and in 1920 had trans-Saharan wireless services there being two stations in the desert. Wireless stations in Egypt and the Sudan connected with Mombasa, Tabora and South Africa.

The World War gave a great impetus to aerial communications, and Cairo became the junction for several services to and from Europe, Asia and the Cape. In 1919 an air route was laid out by British officers from Cairo to Cape Town, aerodromes being built at 24 places by agreement, and their total length was 5,200 miles, compared with 6,823 m. by the Cape-to-Cairo land route. The first attempt to fly across Africa was made in Feb., 1920 by Dr. P. Chalmers Mitchell in an aeroplane chartered by The Times. At Tabora, a little over half way, the machine crashed (Feb. 27). The first to succeed in the enterprise were Col. Sir H. A. van Rynveld and Maj. Sir C. J. Brand, of the South African forces. They reached the Winberg aerodrome, Cape Town, from Durban, and flying away to Natal they were transferred to the Nile, and thence to Dakar. The first regular air service in Africa was established in 1921, its development being connected with the Congo from Stanley Pool to Stanleyville, a distance of 1,616 miles.

3. History.—A summary statement of recent territorial changes affords a guide to the course of events in Africa. In 1910 the British self-governing colonies of the Cape, Natal, Transvaal and Orange Free State were formed into the Union of South Africa, with a single government and one legislature. In 1911 a considerable area of French Equatorial Africa was transferred to the German protectorate of Cameroon, and in return Germany acknowledged a French protectorate over the greater part of Morocco, the protectorate treaty between France and Morocco being signed in April, 1912. In Nov. 1912 a Franco-Spanish treaty defined the Spanish zones in Morocco. In 1912 also Italy annexed the Turkish velayets of Tripoli and Bengazi (Cyrenaica), to which they gave the common name of Libya. In the same year the United States acquired financial control of Liberia, part of its hinterland having passed to France in 1910. In Dec. 1914 a British protectorate over Egypt was proclaimed. In June, 1919, by the Treaty of Versailles (which came into force Jan. 10, 1920), Germany renounced possession of all her overseas protectorates in favour of the principal Allied and Associated Powers. These protectorates were placed under mandates. The Union of South Africa became the Union of South Africa, which became the British Crown and renamed Kenya Colony. As a result of these changes Africa was divided among the following Powers, territories governed under a mandate being reckoned in the possessions of the Powers named:

<table>
<thead>
<tr>
<th>Power</th>
<th>Possessions</th>
</tr>

</tbody>
</table>

These figures give a total of 11,462,000 sq. m. as the area of Africa. In the absence of definite surveys of large areas of the continent this may be regarded as a close approximation to accuracy. In 1914 the German possessions in Africa had an area of approximately 1,250,000 sq. m.; the Turkish possessions (not reckoning the legal suzerainty it possessed over Egypt) an area of some 400,000 sq. miles.

The extinction of Turkish rule in North Africa had long been foreseen and was no matter for regret. It ended a connexion which had lasted five centuries and had been almost wholly evil in its effects. German sovereignty in Africa had dated from 1884 only and had been rapidly enlarged. Endeavours further to extend it had been a prominent factor in German policy for a decade before the World War began, and closely affected very large areas of Africa. Germany desired to secure a footing on the African coast of the Mediterranean and a port on the Atlantic coast of Morocco. These desires conflicted with Italian and French ambitions, and in 1911 the issue on both points was decided against Germany. As to Morocco the Franco-German convention of Feb. 9, 1900, had recognized the privileged position of France in Morocco, but not a French protectorate over that country, and the sending of the German gunboat "Panther" to Agadir in July 1911 was a protest against what Germany considered an unwarranted extension of French influence in Morocco, and an intimation that if German treaty rights in Morocco were to be renounced France must make compensation. According to Prince Bülow, Germany, in 1911—ever never had any intention of taking possession of any part of Morocco England and Spain, besides France, would have opposed us there (Imperial Germany, 1913 ed.). Although this statement may be an after-event reflection the interposition of Britain on the side of France was decisive. Germany withdrew her opposition to the establishment of a French protectorate over Morocco, and accepted compensation in Central Africa. While the Franco-German negotiations were still in progress, Italy, by abruptly declaring war on Turkey and invading Cyrenaica and Tripoli, deprived Germany of her last opportunity—short of war—of gaining a footing in the Mediterranean.

The alternative scheme to territorial acquisitions in North Africa which Germany had prepared were indicated in a note addressed to France on July 1, 1914, during the Agadir crisis. Germany then proposed that France should cede the greater part of the coast and the interior of French Equatorial Africa as far as the Sangha tributary of the Congo river, and further renounce in favour of Germany her right of preemption over the Belgian Congo. These proposals Germany was compelled greatly to modify, but by the convention of Nov. 4, 1911 large tracts of French territory were added to Cameroon. On the south these additions made Spanish Guinea an enclave

1 A mail air service from Toulouse to Casablanca had been instituted in 1920.

2 Including Egypt and the Anglo-Egyptian Sudan.

3 Including the Spanish zones in Morocco.

4 In view of the position publicly assumed by Germany in 1898 of applying to Morocco in general and to Tripoli in particular, Germany had not sought direct rule over the Ottoman provinces in question. Turkish sovereignty was to be respected, but an Austro-Hungarian chartered company had been formed under German auspices for the exploitation of the Saar basin, and the charter Austrian (in effect German) authority would have been imposed upon those velayets, Italy, however, ever since the establishment of the French protectorate over Tunisia in 1881, had "marked" Tripoli and Cyrenaica for herself. See the Memoirs of Francesco Crispi (London, 1914) and H. H. Johnston in Geogr. Jnl. (vol. 44, pp. 280–1).
in Cameroon and gave Germany the southern shores of the Muni estuary. In the east the additions to Cameroon included two tongues of land which gave the protectorate direct access to the Congo river and its great northern tributary the Ubangi.

The Mittel Afrika scheme foreshadowed in 1911 aimed at securing Germany’s supremacy, primarily economic and ultimately political, in central equatorial Africa. The aim was to reserve the Belgian Congo, Angola and Mozambique N. of the Zambezi as a German sphere and thus to link up Cameroon with the South-West and East Africa protectorates. German industries had need of the raw material tropical Africa produces, and moreover the “German race” had needed a field for European settlement. British statesmen were not unfavourable to German expansion in equatorial Africa—so long as it was confined to the economic sphere. In 1898—the year of Fashoda—Mr. A. J. Balfour and Count Hatzfeldt had concluded an agreement which divided Angola and Mozambique into zones in which Britain and Germany respectively were to give financial and economic assistance to the Portuguese. This agreement was capable of various interpretations and in the following year (1899) another agreement, known as the Treaty of Windsor, renewed the ancient rights of Portugal in Angola. In consequence of this agreement the Portuguese that the Balfour-Hatzfeldt agreement was not in derogation of her sovereign rights in Africa. Neither the agreement with Germany nor that with Portugal was published.

After the settlement of the Morocco crisis of 1911 Germany endeavoured to come to a further understanding with Great Britain. Negotiations in regard to the Portuguese colonies in Africa were reopened by Baron Marschall, then ambassador to Britain, and were energetically taken up by Prince Lichnowsky, who came to London as ambassador in Nov. 1912. A new agreement was drawn up and its terms fixed. It affirmed the intention of the signatories to respect the sovereign rights of Portugal and went on to delimit the region in which each party was, as far as the other party was concerned, to have a free hand in respect to economic development. By Prince Lichnowsky, and by the German Foreign Office, the new agreement was looked upon as a stepping-stone to political rights in the regions concerned. By this agreement the whole of Angola up to long. 26° E. became a German sphere, together with the cocoa-producing islands of San Thome and Principe. On the E. coast the whole of Mozambique province N. of the river Likungo also became a German sphere. Originally Belgian Congo was, accordingly, divided between Lichnowsky, the Belgian, and the German Foreign Office, the new agreement, but Germany refused the offer “of alleged respect for Belgian sensibilities.”

In Aug. 1913 the agreement was ready for signature. But Sir Edward Grey, then British Foreign Minister, made it a condition of signing that the 1898 and 1899 agreements as well as the new agreement should be made public, with the obvious object of again reassuring Portugal. The German Foreign Office objected to publication, as detrimental to negotiations for concessions then proceeding with Portugal, and, as Herr von Jagow (then Foreign Secretary) said, because the German press would regard the terms of the Treaty of Windsor and the Lichnowsky agreement as contradictory. Von Jagow said that publication of the agreement would be better delayed until the Bagdad railway treaty—which was looked upon as a genuine triumph for Germany—could also be published. In July 1914 German consent to the publication of the agreement was given—but before the document could be signed the World War had begun.

During the period of these Anglo-German negotiations the French in Morocco, under Gen. Lyautey as resident general, had adopted both a bold and conciliatory policy and had won the respect of the majority of the Moors; the French also steadily developed their West African colonies and had brought under control the region between Lake Chad and the Nile basin.

1. The Likungo lies about 120 m. N. of the Zambezi. The Zambezi valley and all the territory S. to and including Delagoa Bay was reserved as the British sphere. Britain already had the right of preemption over Delagoa Bay.

In the German colonies there was likewise considerable development, notably in the building of railways. It was a period too of material development in the British colonies and of prosperity in Egypt and the Sudan, accompanied in Egypt by manifestations in favour of self-government. In South Africa the alliance of Dutch and British, which had brought about union, had been followed by a reaction among a section of the Dutch, but the majority of the people followed the Prime Minister, General Botha, and his colleagues in their loyal adherence to the British connexion. When the World War broke out it was found that the German authorities in South-West Africa had maintained for years clandestine relations with the German Republic and that they counted, at the least, on South Africa’s neutrality in the war; Germany had also established relations with elements in North Africa inimical to France and Great Britain.

But the British command of the sea rendered it impossible when hostilities began for Germany to succour her colonies. And this led to proposals for neutrality in various parts of Africa. The first such proposal was made, on instructions from Berlin, by the acting-governor of Togoland to the French and British authorities on Aug. 4 and 5, reasons of humanity and the pressing need of the white races to exhibit solidarity in face of the negroes being alleged. This proposal, purely local in scope, was not entertained (see Togoland). Later in the month—Aug. 23—Germany made an offer of neutrality in the conventional basin of the Congo as defined in Article I. of the Act of the Berlin Conference of 1884–5. The Congo Free State, in accordance with the permission given by Article X. of the Act, had proclaimed its perpetual neutrality, and when the Free State became a Belgian colony the obligation of neutrality was retained. No other state exercising jurisdiction within the conventional basin of the Congo had, however, exercised the option given by Article X. of proclaiming its neutrality within that area, which included besides Belgian Congo about half of French Equatorial Africa, a third of Cameroon, all German East Africa, all British East Africa, all Uganda, all Nyasaland, Mozambique N. of the Zambezi, a small part of Northern Rhodesia and the northern part of Angola. Belgium had desired to preserve neutrality in the Congo. At the outbreak of the war M. Fuchs, governor-general of Belgian Congo, had been instructed to observe a strictly defensive attitude, and on Aug. 7 M. Davignon, then Belgian Foreign Minister, asked the British and French Governments if they intended to proclaim the neutrality of their territories in the conventional basin of the Congo. The bombardment of Dar es Salaam by British warships on Aug. 8 was a sufficient demonstration of the British attitude; but at first the French Government seemed disposed to entertain the proposal; so the Belgian minister in Paris informed M. Davignon on Aug. 9. But the French commander in Equatorial Africa had opened hostilities on Aug. 6, and on Aug. 17 Comte de Lahaing, Belgian minister in London, informed M. Davignon that neither Great Britain nor France could adopt his suggestion.

The colonies in the conventional basin of the Congo had thus been proceeding for over two weeks when Germany made her neutrality offer; on the day before it was made the Germans in East Africa had committed the first act of war in the Belgian Congo by bombardment Lukuga, a port on Tanganyika. The German dèmezurche was made by Herr Zimmermann, Under-Secretary in the Foreign Office, to Mr. Gerard, the American ambassador in Berlin, in a note which asked the aid of the United States to procure the neutralization of the conventional basin of the Congo. In a later note, dated Sept. 15 1914, Herr Zimmermann stated that Germany’s object was “to prevent an aggregation of the war which could serve no purpose,” which was not the view of Von Lettow-Vorbeck, the German commander in East Africa, “while prejudicial to the community of culture of the white race.” The Department of State at Washington confined itself to forwarding the German notes, without comment, to the governments concerned. Spanish aid was also sought by Germany. But France and Great Britain refused to entertain the proposals, while, the Belgian Congo
having been attacked, M. Fuchs had been given permission, on Aug. 28, to aid the French in the Cameroons campaign. The efforts of Dutch nationalists in South Africa to save German South-West Africa from invasion were equally fruitless.

In process of time the whole of Africa, except Abyssinia and the Spanish protectorates, was involved in the war (for the operations see the articles on the various countries). The conquest of the German colonies was foreseen in the negotiations which preceded Italy's entry into the war, and Article XIII of the agreement signed in London on April 26 1913 between France, Russia, Great Britain and Italy, said:

In the event of France and Britain increasing their colonial territories in Africa at the expense of Germany, those two Powers agree in principle that Italy may claim some equitable compensation, particularly as regards the settlement in her favour of the questions relative to the frontiers of the Italian colonies of Eritrea, Somaliland and Libya, and the neighbouring colonies belonging to France and Great Britain.

At a meeting of the Supreme Council at Versailles on May 7 1913 it was agreed to form an inter-Allied Committee to consider the application of Article XIII, which had already been the subject of negotiation. Italian desires went beyond the readjustment of frontiers. In north-east Africa she sought a position which would give her all the seaward approaches to Abyssinia. In particular Italy desired to acquire Jibuti, the port of French Somaliland, whence a railway ran to Addis Ababa. This desire was intimated to France in the negotiations preceding the signing of the London agreement of 1913. But Jibuti was the only French port on the Suez Canal route to the East and to Madagascar, as well as the only approach to Abyssinia France possessed, and she declined to entertain proposals for its surrender. Italy, however, obtained from France a welcome rectification of the Tripoli–Tunisia frontier, besides valuable railway and commercial privileges in Tunisia. The claim to extend the hinterland of Tripoli to Lake Chad was refused. With Great Britain the negotiations were prolonged; the British Government, however, assented in 1919 in principle to a considerable readjustment of territorial claims in the Cyrenaician–Egyptian hinterland, that is in those regions of the Libyan Desert in which lay Jibuti and other Senussi strongholds. The basis of the Jazirah was assigned to Italy. In East Africa the British offered an addition to Italian Somaliland by the transfer to it from Kenya Colony of the western part of the valley of the Juba—a rich cotton-growing area—together with the port of Kismayu. This offer was accepted in Sept. 1919, but the Italians desired a larger concession and this led to delays in the final settlement. The proposal to transfer Kassala from the Sudan to Eritrea was not entertained. Meanwhile the area administered by the Sudan Government had been enlarged by the conquest of the tributary sultanate of Darfur in 1917.

The distribution of the German colonies after the war has already been stated. The change of masters was readily accepted by the natives. The war itself stimulated trade in various parts of Africa and led to a development of communications (see page 67, Communications).

Politically the greatest movements in Africa in 1919–21 were the continuance of the separatist campaign by the Dutch Nationalist party in South Africa, and the insistent demand of the Egyptians for independence. These movements are described in the articles SOUTH AFRICA and EGYPT.

Another subject which raised large issues was the position of India and the East Indies. In East Africa, but it was of less importance than the growth of race consciousness among the negroes. Increase of education and of Christianity, the employment of large numbers of Africans in industries, and the lessons taught by the World War, were among the factors which intensified the feeling of racial unity, and led to manifestations of a new anti-white movement—a movement different from the simple objection to interference by Europeans or Arabs previously displayed. The new movement had a consciousness of the need of self-development and progress. Not all the ferment among the negroes was however anti-white, nor was there by 1921 any clear indication what form negro nationalism would ultimately take.

AGA KHAN III. (1877– ). Indian Moslem leader (see I.363). During 1919–21 the Aga Khan's widening influence both on Indian and international affairs was shown in various directions. He had headed the Moslem deputation in 1906 to the Viceroy, Lord Minto, which submitted the case for encouraging abandonment of the studied aloofness of their community from Indian political life; and he was president of the All-India Moslem League thereupon formed during its first constructive years. He initiated the fund, and personally collected more than Rs.30 lakhs, for raising the Aligarh college at Aligarh to university status, which was effected in 1920. The Khilafat period saw him in the middle of the struggle the Aga Khan issued a stirring manifesto showing that the Allies had no overt designs on Islam, and calling upon the Moslems of the Empire to remain loyal and faithful to their temporal allegiance. His immediate followers provided a solid philan of whole-hearted support of Britain, which had a most steadying influence in sterilizing the effects of impatient headstrong elements. Secret missions of great diplomatic importance in Egypt, Switzerland and elsewhere were entrusted to Hs Highness, and enemy anger found scope not only in bitter newspaper attacks but in designs upon his life. His great influence was probably most appreciable in the Khilafat, with leading Allied statesmen and the breadth and liberality of his outlook on the problems of reconstruction. His remarkable study of Indian and Middle Eastern affairs in India in Transition (1918) was not without considerable effect in the final shaping of reforms under the Indian Act of 1919, and was consistent in broad principle with his post-war criticisms of the British Government's Mesopotamian and Arabian policy.

The Aga Khan laboured unceasingly to secure mitigation of the Allied terms toward Turkey, and joined in many representations, public and private, both at the Peace Conference and subsequently, as to the immense importance to Great
Britain, the ruler of the greatest aggregation of Moslems in the world, of not depriving Turkey of a real independent existence. But the issue was complicated by many considerations, and British statesmen seemed less ready to accept his advice in peace than to use his influence to that end. To the G.C.L.E. and the G.C.S.I. there was added in 1916 a salute of 11 guns and the rank and status of a first-class chief of the Bombay Presidency, the only previous instance of the grant of a salute outside the Indian territorial ruling families being that of the first Sir Salar Jung. (F. H. BR.)

AGLIARDI, ANTONIO (1832-1915), Italian cardinal and diplomatist (see 1,377). Noted for his strong patriotic senti-
ments, he actively opposed the Temporist tendencies which prevailed at the Vatican during a part of the pontificate of Leo XIII, and his attitude led to his removal from the diplomatic service to which he was otherwise destined; he was, however, restored to it in 1903, and his influence was of great service in effecting a restoration of the Temporal Power. Agliardi was frankly favourable to the Triple Alliance as the best guarantee of Italy's territorial integrity, and he eventually succeeded in convincing the Pope of the hopelessness of his schemes. With Leo's subsequent social-Catholic activities he was in hearty sympathy, and contributed much to their success. He enjoyed the personal friendship of many of the most eminent men in Italy, including Luigiuzzatti, Antonio Salandra and the Marquis di San Giuliano. He died in Rome March 10 1915.

AGRICULTURE (see 1,388). In the separate article on agricultural administration and regulations in the United Kingdom, and the developments in the United Kingdom during the World War. Developments in the United States 1910-21 are described under the heading Agriculture in the article United States.

I. PROGRESS OF SCIENTIFIC RESEARCH.

During 1900-20 scientific research upon the soil was in the main directed to two sets of phenomena—the interaction of the various groups of organisms living in the soil, and secondly the relation of the various soil constituents to water as a means of interpreting the physical behaviour of the soil under cultivation.

Soil Research.—Dealing first with the latter question, it has long been obvious that the crude view which regards the soil as a mere mechanical foundation for the plant containing a certain amount of plant food—nitrogen, potash and phosphoric acid determinable by analysis—must be abandoned. Inertile soils disclose in the surface layer sufficient plant food for a hundred full crops, and even the later modification of the hypothesis which laid stress not on the "total" plant food in the soil but on the amount that was "available," i.e. soluble in some dilute medium which simulates the influence of water and a solution of an organic acid akin to the cell sap of the plants, failed to provide a means of measuring fertility by chemical analysis. It was the failure of this chemical theory of the soil that led the American investigators, Whitney and Cameron, to propound the view that what really matters in the soil is its water relationships. The plant's roots feed in the soil solution, the liquid medium held on the surface of and between the soil particles by surface tension, and as this solution is always saturated, e.g. with phosphoric acid and potash of which any soil contains more than the soil solution is capable of dissolving, then the actual amount of these solubles present in the soil is of minor importance (so long as a very low minimum) and the extra amount supplied by fertilizers are matters of indifference. Apart from some other factors, it is the water supply that determines the growth of the plant and therefore the fertility of the soil. In its turn this hypothesis breaks down, because it takes too simple a view of the process of solution in the soil, which it regards as a mixture of definite compounds possessing a definite solubility like sodium chloride or other inorganic salts. Actual experiment showed that whenever soil extracts were prepared from soils of different fertility or when even the soil itself was subjected to by means existing within the soils could be removed by mechanical means, they displayed varying concen- tration in phosphoric acid and potash. Moreover the growth of plants in such extracts is, within limits, proportional to the amounts of the nutrient constituents they contain.

The value of Whitney's and Cameron's suggestion lay in the way it dispensed with the solution at all as a means of estimating the plant, and our ideas as to the character and formation of that solution have to be revis.ed in the light of our more recent conceptions of the nature of colloids. A study of the behaviour of any soil towards water, whether we examine such a character as the rate at which water will drain through the soil or the rate at which successive portions of water will be removed from it by evaporation under constant conditions, shows that the soil does not behave as if it were a mixture of mere rock particles of various grades of fineness. An artificial soil built up of particles of ground quartz of the same order of sizes as the soil behaves quite differently towards water, so again the soil that is incompletely saturated with water was a number of the particles, especially those of the smallest size, exhibit colloid properties, which roughly means that they have a special power of holding water on their surfaces more and more tightly as the amount of water diminishes, and also of holding and withdrawing from solutions, the ions, sometimes basic, sometimes acid, of salts. These colloids are probably the particles of compound silicates in the original rock basis; they are akin to the zeolites which can be found in a pure state. The humus or organic matter of the soil is largely colloidal, but the inorganic colloids themselves will accumulate most of the soil.

As regards the water itself, the colloid theory explains certain facts which had much occupied the attention of the American investigators who have been studying the relation of plants to soil under different conditions. For instance, the external drainage of the bad lands. Sachs had long ago shown that a plant would begin to wilt and be unable to take water from the soil before the soil was absolutely dry, again, again, the soil in a "free water" condition will hold plant much more strongly than a sandy soil, wilting occurring when the clay soil has still its 1/10, or more of water in it, whereas the sand will lose water down to 1% before the wilting begins. Various attempts have been made to correlate the "wilting point" of a soil, i.e. its proportion of moisture when wilting sets in, with the "hygroscopic moisture," i.e. the amount of water a dry soil will absorb when in contact with a saturated atmosphere, and with the amount of water the soil holds when wetted and allowed to remain at rest one of these conception mark any change of state; for example the curve expressing the rate at which evaporation will take place from the surface of a perfectly smooth one without any discontinuities, and the points defining the wilting coefficient or the hygroscopic moisture are only particular positions of equilibrium between the water-holding power of the soil particles and the external set of forces tending to remove water. In the same way the distinction between the water held by the colloids and the "free water" in the soil, the latter being regarded as something different in kind and sharply marked off from the colloidal water, cannot be maintained. The colloids must be regarded as absorbing some attractive action on all the water in the soil, though that attraction is infinitesimal when the soil is saturated and only becomes a measurable force when the water has shrunk to small proportions.

The colloids that hold water in the soil are also the agents which control the composition of the soil solution upon which the plant feeds. The soil colloids bring into solution various proportions of any of the fertilizer salts (except the nitrates with which the action is very slight) there is an instantaneous absorption of ammonia, phosphoric acid or potash as the case may be, that is never complete, the extent being determined by such factors as the relative mass of the soil and the fertilizer, the concentration of the solution and the nature of the accompanying ions, e.g. carbon dioxide in the soil solution upholding living, a fertile soil is one possessing a high absorptive capacity, that is as it were pretty fully charged, so that the equilibrium with the soil solution is mobile and the soil colloids part freely with their nutrients to the solution as its strength is reduced through withdrawal of the plant. The analytical methods which attempt to determine say the "available" phosphoric acid by attacking the soil with weak acids really determine something much more complex in which the absorptive power of the soil colloids plays a part. When the soil is supplied with all the phosphoric acid, and then there is a reabsorption, the amount of which is conditioned by the nature and strength of the acid en- dentity. And the result obtained is an empirical one, valid only for comparisons of soils of similar type and constitution, to which limited degree it is of service.

Living Organisms.—The study of the living organisms of the soil has resulted in some reconsideration of the views formerly held as to the relative importance and function of the different groups. Among the earliest of the organisms associated with the soil to be specifically studied were those concerned with the process of nitrification and responsible for the conversion of ammonia (resulting from the breaking down of organic compounds of nitrogen by other bacteria) first into nitrates and then into
nitrate. It was held that as plants (other than the legumes) practically take in all their nitrogen as nitrates, then the rate of nitrate-making or the nitrifying power of a soil would be on one side at least a measure of its fertility. In the course of the experiments on the partial sterilization of soil by heat or antiseptics it has become apparent that the nitrification organisms are very susceptible and may be killed off while the ammonia-making organisms are still active. Again acid soils have been found in which nitrates are not produced. Yet in such soils plants grow freely, taking in their nitrogen as ammonia, not as nitrate. It becomes clear that nitrification is only the end process from ammonia by a supply of lime and appropriate carbohydrates derived from the air and if they are added to a soil containing Azoobacter under conditions favourable to its growth, the carbohydrate supplies the energy whereby the Azoobacter can fix nitrogen or air before the ammonium nitrate is added to the stock of combined nitrogen in the soil. The plant itself fixes no nitrogen, but only draws upon the capital in the soil, restoring whatever it took out when the vegetation is allowed to die back. The soil is enriched by the plant losses of nitrate and nitrogenous matter and by the carbohydrates derived from the air and if they are added to a soil containing Azoobacter under conditions favourable to its growth, the carbohydrate supplies the energy whereby the Azoobacter can fix nitrogen or air before the ammonium nitrate is added to the stock of combined nitrogen in the soil. This in this way the annual cycle of vegetation when the leaves fall back to the soil can result in a yearly accretion of nitrogen which in time may amount to an appreciable fraction of the soil's content of nitrogen. The development of the soil's ability to fix nitrogen in a nitrogenous land is a subject of great importance, and this has been the object of a large number of investigations. In certain soils was derived from the examination of the soils of the wheat field at Rothamsted. The soil of this unmanured plots which has been in arable cultivation for over half a century shows a steady decline in the amount of nitrogen coinciding with the decline in the amount of nitrogen. The yield of several crops of wheat harvested by the crops harvested by the soil in the autumn and winter.

The arable land where the vegetable matter reaching the soil is minimal, only the roots and stolable of the crop, there is a steady loss of nitrogen; on the wildness which may be compared to a natural prairie, the return of the vegetation to the soil causes nitrogen to accumulate not because of the nitrogen contained in its bodies, nor because its carbon dioxide is returned to the atmosphere, but because the Azoobacter, which fixes nitrogen, the Azoobacter group of organisms, though not the only ones capable of bringing free nitrogen into the soil in the atmosphere, is not able to be effective in the soil without the vegetable matter supplied by the vegetable soil but the whole substratum of organic life in the world.

Soil Protoplasma.—The outlook on the organisms in the soil has been entirely changed since Russell and Hutchinson showed the part played by the protozoa in limiting the development of bacteria in the soil. The soil protozoa, which are large, definite animal organisms of varied character—amoebae, ciliates and flagellates—exist in large numbers in all cultivated soils, and as they feed upon bacteria, any conditions which encourage the development of bacteria favor the development of the protozoa. But the soil of the protozoa will increase the multiplication of the protozoa which thereby put a check to the increase of the bacteria. Thus normally the number of bacteria in a soil, however rich and favourable to bacterial development the conditions may be, does not pass a certain limit because it is kept in check by the increasing number of the protozoa. As the fertility of the soil among other things depends on the rate of production by bacteria of ammonia and nitrates from the nitrogenous residues in the soil, the fertility of the soil is also limited by the presence of the protozoa. Certain processes of partial sterilization of the soil, such as heating to the temperature of boiling water up to 170° F, or again treatment for a time with some antiseptic, e.g., chloroform or toluene vapour, affects a selective destruction of the soil organisms. The protozoa are almost entirely killed off, but many groups of bacteria, notably the ammonia-makers, resist destruction though they may be reduced in numbers. But if after treatment the treated soil is placed under normal conditions for growth, the bacteria that remain multiply with great rapidity and rise to a level of numbers and activity they were unable to attain before, because now the protozoa check to their multiplication has been removed. In consequence the fertility of the soil is greatly increased. The fact the yield from a given soil may be doubled. This discovery suggests immense possibilities of increased production from the land but as yet it has not been found possible to apply the method of partial sterilization to ordinary field soils in the open. Heating would be inordinately expensive and the difficulty is to find an antiseptic that combines cheapness with the right degree of
volatility and stability against the attack of bacteria. In greenhouses, however, where the soil soon becomes "sick" through the excessive development of protozoon under the favourable conditions of moisture, temperature and manurial enrichment, the sterilization of the soil by heat has been worked out as a commercial process and is now part of the routine of all progressive cultivators under glass.

Microfungi.—Great as is the attention that is now being given to the soil organisms in all agricultural laboratories there would appear to be room for more work upon one group—the microfungi, of which there is a large flora.

It has been shown that when from one cause or another a soil becomes acid, many bacteria concerned in the decay of vegetable matter are entirely inhibited and may disappear. Fungi instead take up the work, but the broad character of the process remains, the vegetable matter is not burnt away as carbon dioxide but in part accumulates in the form of peat. The formation of a peaty material is in fact a concomitant of an acid reaction in the soil and the activity of microfungi rather than bacteria, and this generalization fits in with many observations of the character of peat deposits.

Often trees are found at the base of these beds where trees no longer grow. It had been supposed that the trees grew on the original neutral land surface when it became fit for vegetation after the close of the glacial epoch. That soil being of a non-calcareous nature gradually accumulates acids arising from the decay of dead matter, and the peat accumulations further the prevailing climatic conditions the further vegetable debris reaching the soil began to form peat. This accumulation of peat in its turn brought about the death of the forest.

Nitrogen.—During 1910-20 agriculture received great benefit from working out on processes on a large scale for bringing nitrogen into combination, processes which thus supplement the comparatively limited sources of nitrogen compounds afforded by the Chilean deposits of nitrate of soda and the ammonia which is recovered as a by-product from the distillation or combustion of coal.

Prior to the World War two processes had been established commercially. At Notodden in Norway air is driven into a specially fashioned apparatus where the pressure being kept between 50 and 100 pounds per square inch of nitrogen and oxygen so that the issuing gases contain about 1:25% of oxides of nitrogen which are then absorbed by passing up towers where they meet an absorbing stream of water or milk of lime. The product, nitrate of lime, contains about 13:5% of nitrogen, and is a most valuable fertilizer, quite as effective as nitrate of soda and on some soils more suitable.

The same time as synthetic nitrate of lime was introduced, another nitrogenous fertilizer was to be manufactured on a large scale, calcium cyanamide or nitrolime. The body arises from the combination which ensues at a temperature of about 600° C. of calcium cyanamide gas and pure oxygen with the resulting formation of a compound which in the soil decomposes mainly into ammonia and calcium carbonate. Cyanamide as a fertilizer requires a certain amount of care in use and care in storage. The solids has proved so effective as nitrate of soda or sulphate of ammonia. Its manufacture, however, received an immense impetus during World War, as it was the simplest and most readily available process for bringing nitrogen into combination from which by further steps ammonia and then the nitrates and acid needed in explosives could be obtained. The United States and many European countries have immensely developed the manufacture of cyanamide, which most in future be available as fertilizer either used directly or after prior conversion into some convenient compound of ammonia.

The war period was also marked by the development on a gigantic scale of artificial ammonia, which had only been finally worked out to the manufacturing stage in Germany in 1913—the Haber process of bringing nitrogen and hydrogen into combination as ammonia. In the presence of a suitable catalyst of iron these two gases will unite at pressures of 250-300 atmospheres and a temperature approaching 600° C., to the extent of 8% or so of the mixed gases. The ammonia can be removed and the remaining gases passed round and round, and it may be said that the greatest difficulty of the process lies in regaining at these temperatures and pressures the Haber process is cheap in power and materials. It was the mainstay of the supply of combined nitrogen for explosives to Germany during the war, and should become a most important source of fertilizer to the agriculturist.

During the war the demand for nitrogenous fertilizers greatly increased about 15% to 20% and in the United Kingdom, there was an increase of about 65% to 80%. Potash for bringing nitrogen into combination with many many plants for the manufacture of synthetic nitrogen products has increased the supply of nitrogen available as may be seen from the following table:

<table>

It should be noted, however, that the 1920 figures are not actual but only potential supply, if existing plants are worked up to their capacity.

Potash.—As the only extensive potash deposits in the world that had been commercially developed—Stassfurt and Alsace—were in German hands, there was during the war a great shortage of potash fertilizers outside central Europe. Great efforts were made to develop processes for the extraction of potash from felspars and other natural sources, but without much success.

The only method which proved of value was the discovery made in the United States that the dust which accumulates in the flues through which the gases from blast furnaces are led contains a considerable amount of potash in a readily soluble form, one-half indeed consisting of sulfates and carbonates soluble in water.

Different grades of flue dust can be collected; the finest is a compound of metallic silicate containing between 60 and 70% of potash. The dust was collected and used for agricultural purposes during the war though only some 15,000 tons per annum were obtainable in Great Britain, and has now worked up for industrial purposes, the output of potash salts from this source cannot exceed a few thousand tons per annum in the United Kingdom. The supply of potash salts for agricultural purposes since the war has been entirely changed by the transfer to France of the Alsaci deposits which occupy an area of some 77 sq. m. between Mulhausen and Colmar in Alsace. This deposit consists of two beds, the upper about 4 ft. thick, the lower about 11 ft., which form practically unbroken strata at an approximate depth of 1,800 ft. and present no difficulties in mining. The material is very uniform in composition, consisting in the main of sylvinit, mixed chlorides of potassium and sodium, containing about 20% of potash reckoned as K₂O. It can be used for agriculture in its crude state and though the development of the field is still very incomplete the former German monopoly of potash supplies is therefore broken down. Another extensive deposit is known in Spain, but it has not reached the stage of commercial development and is generally considered to be controlled by the German company which works the Stassfurt deposits.

Superphosphates.—During the war the manufacture of superphosphate in the United Kingdom was considerably restricted, on the one hand by the withdrawal of sulphuric acid for the manufacture of explosives, and on the other by the shortage of tonnage for the importation of phosphate rock. American supplies were completely cut off and receipts from the North African deposits fell to something like 500,000 tons per annum.

In consequence British farmers were compelled to resort mainly to basic slag of which this country produced about 400,000 tons per annum, though prior to the war only some 280,000 tons had been consumed by British agriculturists. With the extended programme of arable farming the demand for phosphatic fertilizers was greatly increased and the whole of the basic slag produced at home was absorbed, though the output was increased to as much as 565,000 tons from the year ending May 1919. Unfortunately this increase in amount was accompanied by a decline in character owing to changes in the processes generally adopted for making stock.

The Bessemer process has been almost displaced by the open-hearth process which produces a slag less rich in phosphoric acid. The practice has also been adopted of adding fluor-spar to the furnace in order to induce the formation of a more fusible slag, but thereby the solubility of the phosphoric acid of the slag in the work eutric acid generally used in testing its quality becomes impaired. The bulk of the basic slag now sold contains only about 10% of phosphoric acid and if only of the type of slag in which the phosphoric acid is now no longer soluble in weak acids. The new type of basic slag proves, however, little less effective, unit for unit of phosphoric acid, as a fertilizer, but freight charges, always a large item in the cost of basic slag to the farmer, are doubled for the amount of phosphoric acid that is carried, apart from the increase in these
charges per ton. Attempts were in 1921 being made to replace basic slag by finely ground mineral phosphates as a fertilizer for grass land. American experience has always been favourable to these general principles and recent experiments in the United States have demonstrated that they effect in poor pastures the same encouragement of clover as is obtained from basic slag, even upon such un-promising land as the clays in the dry Essex climate. The phosphate rock of Wallingford, that has been found to possess the control of the British Government, may prove of special value for application in this finely ground but otherwise untreated condition.

Plant Breeding.—Probably the plant breeders have during 1900–20 rendered the greatest services to agriculture, inasmuch as improved varieties of wheat have been developed by the introduction of new varieties, giving large yields, better quality and more resistance to disease—are at once appreciated by the farmer and require no alterations in the methods of cultivation. It has been found possible to apply Mendelian principles with comparative simplicity and accuracy to the breeding of new varieties of plants, especially of cereals, and the results achieved have already experienced considerable commercial development in the case of wheat, barley, oats, maize, sugar-cane and cotton. The value of the Mendelian principle lies in the power it gives of combining in one of the selected descendants of a cross-bred individual unrecorded advantages of both parents; if the possibility of the presence of valuable genes.

In the case of wheat Biffen has shown that among the Mendelian characters that are transmitted as unchanged units are such quantitative properties as the resistance to disease, the normal percentage of nitrogen in the grain and the “strength” of the flour resulting from the conditions of the breed. The disease, rust, which is of the ear, as regards English wheat has been an improvement in its strength, i.e., the capacity to yield a spongy elastic dough which will bake into a light loaf of large volume. This strength factor which is connected with the amount of gluten and therefore with the percentage of nitrogen in the flour is as a rule the property of spring wheats grown in a “steppe climate,” with a short period of growth, with considerable heat in the summer months and for greater duration of the most complete dryness before harvest. Wheats from Hungary, South Russia, Manitoba and the great plains of North America possess this quality, and Leclerc and Leavett have shown by sowing the seeds in different states how potent is the effect of environment and climate in determining the percentage of nitrogen and the strength of wheat. As a rule any of the strong wheats brought either from continental or American sources lose their strength completely when grown under English conditions. One wheat, however, of Galician origin but widely grown in America under the name of Red Fife, so widely indeed as to be the dominant constituent of the wheats grown as Market Class No. 2 in America, is a large measure retain its strength in England, the strength in this case being congenital and not the product of environment. Red Fife is, however, a poor cropper on most English soil, yielding but 14 to 15 cwts. per acre, whereas the typical English wheats will yield 25 to 27 cwts. per acre. Biffen has, however, employed it as a parent in the hope of combining the strength of the one parent with the cropping power of the other and one of the results of this cross, a wheat called Yeoman, issued to the public in 1915, is on its congenital soils—the warmer and better soils of the east and south-east of England—probably the heaviest cropper grown. Further, the quality of the grain is so high that the miller can use it without any mixture of strong foreign wheats, such as are necessary to the extent of 40% or more with ordinary English wheats. Another of Biffen’s wheats, Little Joss, by its power of resisting rust, has proved a very heavy cropper and is extensively grown on soils that remain fairly dry throughout the winter. Saunders in Canada has effected a very considerable extension of the wheat area by the introduction of a wheat called “Marquis,” another hybrid with Red Fife as one parent, which is now the best of the good quality wheats grown in the northern province of Canada. In a part the extension of Marquis may be put down to its superior cropping powers, but for one reason or another it has largely displaced all other spring wheats in the North-West. In 1910 the area under spring wheats in the Province of Manitoba, which is largely inhabited by the Saskatchewan and Alberta was estimated to amount to 20,000,000 acres and the crop in Canada alone to 129,000,000 bush. —all the produce of what was but a single plant in 1903.

Immunity from Disease.—The inheritance of immunity from disease is best illustrated by the discovery of potatoes immune to wart disease. About 1897 attention was drawn to the prevalence in certain parts of England and Wales of a disease of potatoes, generally found in old cottage gardens and allotments, which causes the potatoes to degenerate into a mass of dark corky excrescences and will in bad cases destroy the crop entirely. The disease is due to the attack of a lowly organised fungus, and the difficulty of control due to the fact that once established in the soil the spores or some resting form of the fungus retain their life for an indefinite period of many years. The soil has become infected with no practicable means has been found of clearing it; even leaving the land down to grass for ten years has been found ineffective. Considerable areas in the industrial districts of Lancashire, Cheshire, Stafford and Shropshire, where the land has been subject to the disease and it unknown to a greater extent of seed potatoes in 1917, which caused men to plant anything that was available without inquiring into origin.

The consequences would undoubtedly be the complete destruction of potato-growing in those districts had it not been observed that one or two types of potatoes could be found unharmed in some of the old infected gardens. Further examination proved that these varieties were really immune to the disease, however, heavily infected the soil, and though in themselves they possessed little commercial value they were at once employed as seed varieties and have become the source of a new race of potatoes immune to wart disease. Many of these are now proving to be good market varieties of heavy cropping power, and by their aid potato-growing in these districts has been re-established, and it is probable otherwise inevitably would have spread until the whole country would have been involved. As the disease has also obtained a foothold in the northern habitations of Belgium and Germany, the value of this discovery of immunity is difficult to overestimate. From the study of this and other cases the conviction grows upon the most fruitful method of dealing with disease and other dangerous factors, is the search for immunity rather than by methods of treatment.

Selection.—In the improvement of cereals considerable advantages have been derived by working on another principle than that of breeding, i.e., pure line selection. Very little improvement in a variety can be effected by what may be called “mass selection.” If in going over a field of wheat a selection is made of the longest ears, or again if the heaviest grains are sorted out, no perceptible improvement is visible in the crop grown from the selection, not even if the process is repeated generation after generation. The superiority of the individuals selected has been due to some accident of nutrition and is not transmissible to the offspring. If, however, the selected individuals are sown separately, here and there among them will be found one which in the next and succeeding generations still preserves some superiority which is congenital to it and is maintained in succeeding generations even when the seed is worked up to a large crop.

An ordinary variety, say of wheat, really consists of an indefinite mixture of sub-varieties each of which, for many generations, is selected at large scales true in itself, i.e., self-fertilized. This “pure lines” may be selected from single seeds of such self-fertile plants and worked up to commercial stocks of seed. These plants may, however, be crossed one with another and, when crossing power over the mixed variety from which they are derived, and are also appreciably more uniform in such details as time of ripening and length of straw. It has become evident that every commercial variety of cereals, even if of deliberately cross-bred origin, will be improved by pure line selections from time to time.

Nutrition.—It was still difficult in 1921 to discuss in any detail the progress that is being made in the study of animal nutrition, in regard to which the teachings of the scientific man have had much less effect upon the practice of the farmer than has been the case when the nutrition of the plant has been considered.

The great shortage of cattle food during the war, notably in 1917 and 1918 when no tonnage could be spared for cattle food, did reveal two things, first, the dependence upon imported corn and oil seeds that British meat and milk production had fallen into, and secondly, the necessity for waste products to be utilized which the normal output of meat, milk and other animal products did not represent one-half, possibly not more than a third, of the amount that must be obtained in order to make the present system of feeding livestock a proper informed practice. At the same time certain lacunae in our theory were disclosed, which prevent the scientific man from setting out with any accuracy the limits within which the fattening of animals will proceed most economically. It will be seen that the problem is a very complex one. On the one hand, as regards the amount of food fed over and above the maintenance ration, the law of diminishing returns is found to hold for the amount of daily increase; on the other hand, the slower the rate of fattening, the
greater must be the non-productive consumption of food on maintenance only. Again in the later stages of fattening the law of diminishing returns may, as in fashion, take another form, and may be put as offal fat of comparatively low value instead of as edible fat in the "meat" portions of the carcass. Much more exact information is therefore being sought as to the incidence of the improvement of the consumption of food and again to the changes in the composition of the carcasses as the fattening process advances.

Concerning the nutrition question recent work upon "vitamines" and accessory food factors is found to have its application to questions of animal nutrition. Not only the health and growth of certain animals, notably pigs, is in practice affected by the deficiency and the performance of a cow, a sort of index number, but also the fattiness of certain accessories—meat or butter, whatever may prove to be their function. In practice the path of safety for all farm animals lies in a reasonably mixed diet, which includes some proportion of uncooked green food. Pigs and poultry have not infrequently been sufferers from diets insufficiently supplied with vitamins.

Animal Breeding.—Although in 1921 such progress had not yet been made with the very complex subject of animal breeding as to enable economic results to be obtained similar to those which had accrued in plant breeding, still the ground was being prepared by certain initial investigations for the mode of inheritance of some of the desiderated qualities in domestic animals, e.g. size, prolificacy, quality of wool, etc.

Punnett, for example, in England has thrown some light on the inheritance of size of wool in the sheep, and again on the inheritance of fur, but by far the most important work in this direction has been done by Pearl in Pennsylvania. In studying the inheritance of milk yields he has first of all endeavoured to obtain a single figure characteristic of the performance of a cow. He has undertaken a study of commercial milk records and has constructed a type curve showing the variation in milk yield for a cow during successive calvings, whereby if its milk yield in any one year is known this figure can be corrected to give the milk yield in the standard year used for comparison. A similar type curve can be constructed for the period of a lactation, whereby the yield for the whole period can be deduced from the yield ascertained during a particular month or less. Having thus obtained characteristic figures for cows, Pearl was in a position to compare the performances of cows with their offspring by different bulls. By tabulating all such comparisons obtainable with regard to the particular bull a characteristic mark is obtained for the bull. Some bulls are found always to bring about an increase in the milk production of the daughter over the dam; other bulls which had a great repute in their day and a fine record in the show yard equally invariably yielded the same mean yields as their dams. The value of this work in connexion with milk recording and breeding is evident; indeed in Denmark for some years the underlying principle of the work has been that of the bull's performance being transferred from the sire to the progeny. The difficulty attaching to the application of these results lies in the disinclination of farmers to retain bulls for service for more than two or three years; they are carried before there is any opportunity of testing the milk-producing quality of their offspring. (A. D. H.)

II. ADMINISTRATION AND LEGISLATION IN THE UNITED KINGDOM

As was inevitable, the World War gave rise in all countries to a great body of emergency enactments and temporary legislation affecting agriculture. Beyond these, however, the years 1917-21 saw a large volume of legislation which aimed at the reorganization of agriculture in Great Britain, and also inaugurated a definite agricultural policy, the main features of which found expression in the Corn Production Act of 1917 and the Agriculture Act of 1920. The principles underlying these Acts were first set out in the report of the commission appointed in 1915 under Lord Milner, and still more fully in the report of the sub-committee of the Reconstruction Committee under the chairmanship of Lord Selborne.

Briefly, these committees found that the position of the United Kingdom had, as demonstrated by the war, fallen into great insecurity in consequence of the neglect of agriculture which had been going on during the previous 40 years. In 1872 the arable land in the United Kingdom amounted to nearly 24,000,000 ac., and this had become by 1914 little more than 10,000,000 acres. The loss had been experienced chiefly in England and Wales, where the shrinkage had been nearly 4,000,000 ac., from 14,043,000 to 10,998,000 acres. This represents a great decline in the gross production of food, because it has been abundantly demonstrated that a acre of medium land under grass does produce only about one-third of the meat or milk that can be obtained from the same land if it is put under the plough and the crops are consumed by stock. Moreover, wherever there is a definite shortage of food the production of meat is in itself a wasteful process, from seven to ten pounds of real food being consumed by the animal in making one pound of food in the shape of meat or milk. The only gain in meat production is that the animal is able to convert coarse fodder like straw and waste materials like millers' offals into human food, but an animal like a pig, which is largely fed upon barley and maize meal, equally edible by human beings, becomes definitely wasteful of the resources of the country when a real food scarcity is declared. The comparison between the productiveness of grass and arable land may perhaps be illustrated most markedly by a consideration of the potato crop. An average yield of potatoes in England is about 61 tons per ac., which represents over 2,000 lb. of dry food when all allowances have been made for waste. Under grass the same land would not produce more than 120-150 lb. of meat, i.e. about 100 lb. of dry food, or 150 gal. of milk, i.e. 170 lb. of dry food. Nor does the animal food, pound for pound of dry matter, possess more than a slight superiority over the potatoes in its power of maintaining human beings.

Beyond the War.—Roughly speaking, in the years immediately preceding the World War the United Kingdom was only producing about 42% of the food consumed by its people. The greater portion had to be imported, and this applied particularly to wheat of which only about one-fifth of the normal consumption was produced at home. This dependence of the nation upon external supplies of food was its great weakness revealed by the war. Not only was there the danger that the German submarine campaign might prove successful and force submission by starvation, but, even as it was, the country's effort was hampered by the necessity of allocating to food supply so large a proportion of the available tonnage needed for other purposes of which consuming power is not at present needed. At the same time, the purchasing power and credit of the country were continually impaired by the enormous sums spent abroad for food.

The external food bill amounted to over £250,000,000 a year before the war, and during its latter stages this had risen to three times that sum. The enemy was not slow to realize that this was Britain's vulnerable spot. The attack failed, but the economic consequences pressed grievously upon Great Britain after the war. The recovery of Britain was deferred by the enormous purchases it must continue to make abroad in order to keep its people fed, and the sacrifices it must make in order to maintain the foreign exchange at a high level in order to meet these purchases.

It had often been argued that in case of emergency the grass lands of Britain constituted a great reserve of fertility which could be drawn upon for the growth of corn and other crops, but when the occasion came it was proved how little of this reserve was immediately available. Neither the men nor the horses, not even the buildings or the implements, required for arable farming, existed any longer. All the inertia of the farming community came into play against conversion, and despite the War Finance (State Aid, etc.) Acts, with compulsory powers, proffering compensation against loss and assistance in arming and converting lands and machines, and less than a further 2,000,000 ac. of grass land got broken up during the fateful years of 1917 and 1918. Once the art and means of arable farming have been lost, it is only slowly and at great expense that they can be improvised.

Concurrently with the decline in the production from British land in consequence of the conversion from arable into grass there had been a corresponding decrease in the agricultural population, which in England and Wales alone had fallen from
Agriculture

1,260,371 in 1871 to 951,674 in 1901, though by 1911 it had again risen somewhat, to 1,002,743.

This reduction of the agricultural community was not to be viewed with equanimity. A population dependent entirely upon manufactures gives rise to an unstable State, subject to violent fluctuations of prosperity because the causes that determine employment are apt to affect all industries simultaneously. Political and war taxation is prohibitive and labor and wages, just as it is healthier and more reproductive and both physically and temperamentally better fitted for steady enduring work.

It was these two motives then that led to the legislation under review—the desire to ensure a greater production of food and the better cultivation of British land, and the desire to increase the rural population, neither of which could be attained if the old laissez-faire policy were persisted in.

New British Policy. What had been the origin of the dangerous situation in which the nation found itself in 1914? Taking extent of the arable land as an index, the high-water mark of English agriculture was reached in 1872. The later seventies were marked by bad seasons culminating in the disastrous experience of 1879. At the same time rapid progress was being made with the opening up of the American prairies for corn-growing and with the cheapening of ocean freights. This was a period of immense expansion in the new lands of the world; it saw the growth of the Middle West both in the United States and Canada, the agricultural settlement of the Argentine and other South American lands, the development of Australian wheat-growing areas and the commercial exploitation of southern Russia. As a consequence, prices of the great agricultural commodities, corn and meat, fell rapidly and continuously during the eighties and nineties. Wheat from an average of 54s. 8d. per qr. in 1871-5 fell to 23s. 10d. in 1894; the average return per acre on an arable farm for both corn and meat, estimated at 16s. in the first period, dropped to about 10s. between 1864 and 1900. As the rate of wages rose during the period and no great compensating factor was at work (other than the perfecting of the self-binder, which had made wheat-growing for export possible in the new countries), British farming was unable to adjust itself with sufficient rapidity to the vastly diminished returns. The great depression resulted in the ruin of a large proportion of the old farmers, in a wholesale loss of capital and skill, and in the enforced closure of vast areas of land which had ceased to control the prices of its main products. The industry met the situation by a drastic reduction of expenditure and the conversion of arable land into grass on which the labour bill was small. The process was aided by the continued development of the milk trade. From 1900 onwards the course of prices turned upwards—the world’s population was growing up to the food supply, and the new farming adjusted to the changed conditions began to become steadily prosperous. But the memory of the great depression remained, confidence was small and capital mistrustful. Men hesitated to adventure their money in a business which was liable to a break of prices such as had occurred within all too recent a date. Such were the conditions that had led to the dependence of the nation upon foreign food and particularly upon foreign corn; hence the object of the policy was to give the arable-land farmer security that he should not in future be subjected to a devastating break in prices such as had occurred in the eighties and nineties of the last century. With this security in the background it was thought the current conditions would be favourable enough to bring about an extension of the arable area.

The Prime Minister said in his famous speech to agriculturists in Oct. 1910:

"The Agricultural industry is the greatest industry in the State. It ought therefore to be a primary concern of every Government and of every Statesman to do what in them lies to promote that industry. I regret to say that civilization has been the victim of a bad system during the last generation to foster agriculture. I hope that record will now be rolled up and that there will begin a new era in the relations of the State with the greatest and the most important of its industries..." The question is 'Are we going back to the dismal pre-war conditions or are we merely going to maintain the progress which has been made?' Are we not going further? There can be but one answer from every man who loves his country. We must go forward. How is it to be done? You must have a settled policy with regard to agriculture. The first condition is security to the cultivator; security in the first place against ruin through the violent fluctuations of foreign agriculture."

Acts of 1917, 1919, 1920. The method by which this security was given in the "Corn Production Act" of 1917 and the "Agriculture Act" of 1919 embodies a novel principle. Instead of a protective duty, which enhances the price to the consumer, a bounty was given to the producer if the average market price of wheat or oats fell below certain guaranteed figures. In the Corn Production Act certain guaranteed prices were set down for six years ahead, but at that time it was vain to make forecasts of the trend of prices, and actually none of the guarantees then given ever came into operation. By the Agriculture Act of 1920 basic prices of 6s. or 46s. was varied in like proportion. If for example the commissioners found that in 1939 the cost of production of a quarter of wheat was on the average 20% less than in 1919, the price guaranteed by the Act would become 54s. 9d. Should then the average price actually obtained by farmers, as ascertained by the official commissioners, be lower than the guaranteed figure for any quarter of wheat or oats, the Government would be liable to pay 1s. 6d. per quarter on all the wheat produced. But since the verification of the actual quantities grown presents great administrative difficulties the crop is assumed to be 4 qr. to the acre, and the undertaking of the Act was to pay four times the difference between the average realized price and the guaranteed price on every acre of wheat grown, five times the difference in the case of oats, on the assumption of an average crop of 5 qr. to the acre. It will be seen that the pay-out of the Act would be designed to encourage the farmer to accept the guaranteed price if he happened to obtain for his particular sample. The normal course of trade is not interfered with and the grower gets the benefit of any superiority of quality or favourable market conditions he may possess.

The guarantees were confined to wheat and oats, not so much to increase the specific production of those cereals as to encourage arable farming, since one or both of these crops formed an inevitable part of every rotation in the United Kingdom.

Inevitably the State was involved in a considerable liability in any year in which a break in prices might occur after harvest but in which the cost of production was based on pre-harvest figures. This was, however, precisely the occasion to which the ministerial mind of the past, and the Act was designed to give the farmer such assistance of the credit unions that had not been possible at those times. The State, however, only accepted this liability in order to bring about an increase of production; it recognized an obligation towards agriculturists, but on the other hand it required that the land should be put to proper use. In the Corn Production Act the Board of Agriculture was given power to enforce proper cultivation where the rules of good husbandry were being neglected and also to dictate the mode of cultivation or the use to which the land should be put for the purpose of production of increasing food of which the public interest. In case of failure to comply with the directions the Board could cause the owner to terminate the tenancy, or, if the occupier were not the owner, could sell the land itself and cultivate. These somewhat drastic provisions, which were exercised under the Defence of the Realm Act during the war, were strongly opposed by both owners and occupiers and became greatly modified when the Agriculture Act of 1920 was passed. Under the new Act the powers of the Ministry of Agriculture were limited to the enforcement of cultivation according to the rules of good husbandry.

We are, however, another public interest to be considered—
Land drainage for generations has been a subject of legislation, but it was evident that existing powers were inadequate to provide for the efficient management of the drainage of the majority of the river basins of England and Wales. In many areas there was a marked deficiency of adequate authority, so small and isolated were the rating powers to be able to carry out works falling within their area but vital to the whole river basin. In other cases the area was inadequate or the existing commissioners of sewers failed to execute their duties efficiently. The Acts, therefore, were designed to give the Ministry of Agriculture powers to make orders constituting drainage districts, altering the boundaries of existing drainage areas or enlarging their powers of levying rates or borrowing. The Ministry may also act in default of any drainage authorities or may delegate to a committee of the county council or councils of the area concerned, though its powers of executing any such work of drainage and improvement was limited to any scheme submitted and fixed by the Ministry at not more than £5,000. By means of these Acts and of the Defence of the Realm Acts possessed by the county executive committees, much valuable work had been accomplished by 1921 in clearing the smaller watercourses and improving the drainage of minor subjects to flood or unirrigated because of waterlogging. Large schemes exist for dealing comprehensively with important areas like the Ouse basin, which embraces some of the most valuable land in the Fens, but these schemes are likely to remain in abeyance while the difficulties of financial stringency and high cost of labour prevail.

One of the heaviest tasks which was assigned to the Board of Agriculture at the close of the war was the settlement upon the land of such ex-service men as desired holdings and could show their suitability to occupy land. Under the Small Holdings and Allotment Acts, 1913 and 1914, the War Agricultural Crop Production Act passed by the Ministry of Agriculture, and the Corn Production Act of 1918, a very large number of holdings were created, and the Ministry of Agriculture appointed county executive committees in order to carry out the orders under the Defence of the Realm Acts for the increase of food production.

It may be noted that with one or two comparatively small exceptions the minimum wage regulations succeeded in avoiding strikes in the agricultural industry during a period in which labour conditions were abysmally bad. The Corn Production Act, and in its turn the Agriculture Act, thus represented a definite attempt on the part of the State to frame a constructive policy for agriculture in the national interest. The two main purposes of the former act were to give the farmers a better security of a return for their work, the State obtaining increased production and some control over the use of the land. It should prove, however, that even with guaranteed prices the occupiers of land—landlords, farmers, and cottagers—would lose if the regulations made by the State under the guarantee, the purpose of the Act would be unfulfilled. To meet this the Act gave the Ministry power by Order in Council to fix the rates, and the regulation was that no occupier of holdings of land shall be liable to pay rates at a higher rate than the rates of fourpence in the pound on the value of the land. The Act also provided that no occupier of holdings of land shall be liable to pay rates at a higher rate than the rates of fourpence in the pound on the value of the land.

It may be noted that the Agriculture Act contemplated the delegation of the powers of the Ministry to control cultivation to committees of the county agricultural committees which were set up by the Ministry of Agriculture Act of 1919. This was a continuation of the work of holdings and it was under the Act that the county councils were given powers to hold and equip for small holdings, but it was necessary that the schemes framed for this purpose should show a reasonable prospect of being self-supporting on the rents that could be expected from them. The rents of ex-service men could be affected under such terms. Not only had the price of land, especially of land suitable to small holders, increased during the war, but a great number of small holdings and adaptation, necessary in the majority of cases before a small holder could be placed upon the land, had grown to three or four times their pre-war magnitude. No such rents could be charged as would make the small holdings remunerative, and it was by the revision of rates and the elimination of the losses that would accrue if the holdings were let at reasonable rents. Accordingly, by the Land Settlement Act of 1919, the State accepted this liability and allotted a sum of £50,000,000 for the purpose of making a compensation to the county councils as the agencies for the provision of small holdings, and strengthened their powers to acquire land compulsorily for the purpose by purchase or by hiring. In the main the £20,000,000 mentioned above has been lent to the county councils in order to enable them to acquire land and adapt it for letting as small holdings.

The county councils could not take up such loans, did not the Act require them to pay interest on such borrowings for the purposes of the Act to pay to the county councils any losses they had incurred in the provision of holdings under approved schemes. The loss each year consists of the excess of the loan charges over receipts for rent and charges. The total losses which had accumulated up to 1921 was £1,500,000. The liability as compensation to the county councils was estimated, as regards Scotland and Ireland, to be £4,000,000, and nearly £1,000,000 in England and Wales. The total liability was therefore estimated at £5,000,000.

The liability of the county councils was as regards Scotland and Ireland, to be made good by the Ministry of Agriculture and Fisheries. The Act also provides for the setting up by the county council in each county and in certain county boroughs of an agricultural advisory committee to deal with small holdings and allotments, with the powers to regulate cultivation delegated to them by the Ministry under the Corn Production Act of 1918. A drainage committee may also, by the direction of the county council and with the concurrence of the Board of Education, take over from the Education Committee the control of agricultural education.

In 1919 the Ministry of Agriculture and Fisheries Act was passed, which involved changing the title of the Board of Agriculture, set up under the Agriculture Act, into a council of agriculture for England and Wales, partly elective and partly representative, which should meet at least twice a year for the purpose of discussing matters of public interest relating to agriculture. The council is also empowered to acquire land for agricultural purposes or to hold it or to delegate it to local authorities. The council may hold or acquire land and be free from any liability for the debts of the council, and may make any regulations necessary for their purposes. The council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council.

The council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council.

The council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council.

The council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council.

The council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council has power to provide for the payment of compensation to any person whose land is acquired by the council, and to the order of the council.
Education and Research.—From the administrative point of view the chief advance effected during 1900–20 was the organization throughout the United Kingdom of a scheme of agricultural education and research. State assistance to agricultural education may be said to have begun with the Technical Institutions Act of 1889, but the scheme of research and experiment which it provided practically unprovided for until the setting up of the Development Commission in 1908. The scheme then adopted was furthered by the allocation of fresh funds for the purpose after the end of the war, and most of the institutions contemplated were at work in 1921.

The essential feature of the scheme is the provision of institutes, each dealing with a particular aspect of the subject and as a rule associated with a university possessing an agricultural department. The State exercises no direct control over the nature of the investigations conducted, other than the sanction accompanying its annual contribution, which is in the nature of a grant in aid. General policy is also reviewed at the meetings of a research council composed of the directors of the institutes and officials of the Government departments concerned. The staff of the research institutes are not civil servants but are engaged by the respective governing bodies; the State does, however, provide for a stated scale of salaries with increments and superannuation allowances. The annual expenditure on the scheme amounted to £416,000 for England and Wales for the year 1921–2, and to £5,400 for Scotland for the same period, but the Irish expenditure cannot so easily be differentiated from the other commitments of the Department of Agriculture.

The Experimental Station at Rothamsted, the oldest in the world, as it has been greatly enlarged and developed as the Institute of Research in pedology and plant nutrition, to which has recently been added a second institute dealing with plant pathology, embracing entomology, mycology and helminthology. At Cambridge, where the main research is in connection with the vegetable and fruit industries, has been added a second institute dealing with animal-breeding from the genetic side and with problems of reproduction, and the plan was to draw all these threads together so as to make at Cambridge an institute dealing broadly with animal husbandry in all its aspects.

Research in dairy problems is provided for by an institute in connexion with the University College at Reading, and a second station was projected in 1921 in connexion with the Agricultural College at Glasgow. The plant-breeding station and institute proper are situated at Cambridge; a second station, specializing mainly on ground-clovers and clover-grass crops and experiments on the management of the pastures, is associated with the University College at Aberystwyth; and a third station was planned in 1921 in Scotland. The commercial development of the products of the plant-breeders is provided for by the National Institute of Agricultural Research, which has recently been set up at Cambridge largely by contributions from trade sources.

Research in fruit-growing problems is dealt with by an institute at the University of Bristol (Long Ashton) and a second station situated at East Malling in Kent, further sub-stations being in contemplation at Cambridge for the eastern counties fruit district and elsewhere. The Bristol station is also dealing with cider-making and with the various processes of fruit preservation, to which end a small commercial factory is maintained at Chinning Caden.

The Imperial College of Science in London maintains an institute for work in problems of plant physiology, utilizing for its experimental cultures various institutions near London, such as Rothamsted, the Lea Valley Experimental Station which deals with glass-house problems, the East Malling Fruit Station, and the Experimental Breeding Station of the Royal Horticultural Society at Wisley. The latter station should also be made of the John Innes Horticultural Institute at Merton, which under Mr. W. Bateson deals mainly with genetic problems, though this institute derives its income entirely from trade sources.

Schemes for dealing with research on problems of agricultural machinery and again with veterinary science were under consideration, but the foremost body already in existence directly concerned with research is the laboratory maintained by the Ministry of Agriculture.

The complete scheme also provided an annual sum for grants in aid of research investigations set on foot by individuals who are not attached to a research institute, and again for postgraduate scholarships in order to ensure a supply of properly trained workers. Higher instruction in agriculture is provided for by agricultural colleges, which as a rule are attached to one of the local universities and have a distinct regional responsibility as to the provision of information and technical advice to farmers occupying land in the area allocated to the college.

In Scotland three such colleges are attached to the universities of Aberdeen, Edinburgh and Glasgow; in England there are departments of agriculture attached to the universities of Durham (Newcastle), Leeds, Cambridge, Reading (Oxford), and in addition four residential agricultural colleges—the Harpur Adams College at Newmarket; the South-Eastern Agricultural College at Wye, Kent; the Midland College at Sutton Bonnington and the Scalloway Bay College at Newton Abbot, Devon. In Wales the University College at Bangor is associated with a station department of the local Agricultural Society.

Intermediate education in agriculture is given at the Royal College of Science in Dublin and the Albert Agricultural College at Glasnevin, while there are professors of agriculture at the Queen's Universities at Belfast.

Intermediate education in agriculture is also given at the agricultural colleges through extension lecturers attached to the various colleges. In England and Wales the county councils are the responsible authorities. The Association of Agriculture provides an agricultural organizer for each county and gives assistance towards the setting up of a farm institute, intended in general to be a series of local agricultural colleges, and to serve as a colt-removal for the long periods demanded by the agricultural colleges. In Ireland intermediate instruction in agriculture is given at the Munster Institute, Cork, the Ulster Dairy School and the four regional agricultural stations at Athenry, Ballyhaunis, Clonakilty and Strabane.

Steady progress has been made in all parts of the United Kingdom in the schemes for the improvement of live stock, by the dissemination of the smaller scale of the experimental work, and on the other hand the scheme came into operation in 1911, premiums, to which both the Department and the local authorities contribute, are given towards the purchase of approved stock and other required improvements. Therefore the assistance is maintained in the improvement effected in the quality of the store cattle exported for fattening to Great Britain. In England and Wales farmers are encouraged to form societies for the purchase of bulls or heifers of a stallion character for fattening, towards the cost of the sire, which in the case of a bull may not exceed 50 or one-third of its cost. The work of forming societies for recording the milk yield of the cows of the members has been vigorously prosecuted, and the growth of the movement is shown by the fact that 637 cows obtained certificates in 1915 and 1,211 in 1921. The high prices obtained for recorded cows and their progeny show the value that farmers attach to milk records.

III. The War Period

For a long time after the declaration of war no special effort was made in the United Kingdom to develop agriculture and increase production of food. A measure to prevent the slaughtering of calves and pregnant animals was passed in 1914, but no other legislative action was taken until the close of 1916. Proposals which had been made, such as those of the Milner Committee, to guarantee a price for wheat or to give other bounties on production, were turned down on the broad principle that any interference with the free play of the market would impair the confidence of the trader and reduce importation to a greater degree than the increase in production. In 1915 in response to the general feeling farmers had increased their acreage of wheat by 450,000 acres and of oats by 200,000, but this increase had chiefly been attained at the expense of the barley crop, for there had been no increase in the total extent of barley under the plough. In 1916, however, the wheat area went back by 280,000 acres, and a low yield per acre was obtained. The potato crop was also much below average. It may be noted here that, speaking generally, except in the magnificent harvest of 1914, the seasons during the World War were very adverse to arable cultivation, being characterized by wet seeding-times and harvests, with spring droughts. It was not until 1917–8 that there was a favourable autumn and spring for sowing, but that promise was belied by a disastrous harvest-time for all the western and northern parts of the kingdom, with rains so heavy and protracted that an inconceivable proportion of the corn crops were never harvested.
Agriculture

Wheat Supplies, which assumed complete control of the purchases of wheat and the operations of the milling trade, was followed by the appointment of a Food Controller and a promise in Dec. of certain guaranteed prices for wheat, oats and potatoes. At this time Rowland Prothero (afterwards Lord Ernle) had become President of the Board of Agriculture, and he proceeded to set up a Food Production Department which would take charge of a national effort to obtain more food from the land. This department came as chief Sir Arthur Lee (afterwards Lord Lee of Fareham).

The policy adopted aimed at obtaining an increased acreage of arable land and as large a proportion of wheat and other broad corn as possible. Success depended upon the enthusiasm of the farmers, upon securing additional labour and upon assisting the farmer to obtain supplies of all kinds—horses, tractors, seeds and manures.

The first step was to set up War Agricultural Committees in each of the counties of England, Wales and Scotland; in Ireland the existing statutory County Council Committees on Agriculture were available for the same purpose. In England smaller executive committees were afterwards appointed, to whom were entrusted in the main the special powers which had been conferred by D.O.R.A. on the Board of Agriculture. District committees, and even in some cases parish committees, were further appointed. The staffs required for the executive committees were made up from the council county staffs and officers of the Land Valuation Department and Inland Revenue, while district commissioners appointed by the central department for small groups of two or more counties served to bind the whole organization.

As it was already Jan. 1917 before the Food Production Department was set up, it was impossible to effect much increase in the crops of that year, and in practically all cases it was obtained by voluntary response to the appeal for greater production. In Glasgow the committees, and even in some cases parish committees, were further appointed. The staffs required for the executive committees were made up from the council county staffs and officers of the Land Valuation Department and Inland Revenue, while district commissioners appointed by the central department for small groups of two or more counties served to bind the whole organization.

Speaking roughly, about 40% more grain was produced in 1918 than in 1916, and if the potato crop is also taken into account the 1918 crops represent a saving in tonnage (and shipping was the limiting factor in the prosecution of the war at that time) of 2,600,000 tons. Results would have been even better if it had not been for the disastrous harvest weather, which caused the total loss of something like 5% of the grain crop, and rendered even more unfruitful for any other purpose than cattle-feeding. The occurrence of so continuous a succession of heavy rains was naturally regarded by the opponents of "ploughing up" as a justification of their adherence to grass. It did indeed put an end to the plans which had been made for a further extension of the arable area in 1910. Work on most farms had fallen badly into arrears, and land had become foul and weedy, so that it seemed preferable to concentrate the available labour on the existing acreage without consideration of the character of the land. But the mistakes made, if one is to judge by the mass of the results afterwards realized upon the broken-up land, affected but a small proportion of the land ordered to be put under the plough. The opposition both of occupiers and owners to the plough policy must be set down to the grass-land tradition, which the great depression of 1880–1900 had so firmly impressed on English agriculture.

None the less the programme was adhered to, and, aided by favourable weather in the winter and spring of 1917–8, a remarkable increase in the cultivated area was achieved. The disturbed state of Ireland prevented the realization of the plans which had been formed for a still further increase of 5% in the cultivated area. The tables show what was actually obtained in each of the three countries.
tillage land rather than to attempt to increase its area in the face of the general opposition of the agricultural community.

**Labour Supply.**—Turning now to the means by which this increased production was realized in war-time, the prime difficulty experienced was the lack of labour. Grass land had often been described as a reserve of fertility that in case of need could be converted into crops, but this view had ignored the facts that laying down to grass is accompanied by the permanent loss of men and horses, implements and even buildings. When the need comes tillage cannot be resumed at pleasure; the men and machinery are no longer there. In Jan. 1917, when the food production campaign began, the 800,000 men employed in agriculture in 1914 had fallen to 562,000, and as about 180,000 of these were of military age and fresh drafts were urgently needed for the army, some new sources of labour had to be tapped. The operations of voluntary recruiting, and the action of local tribunals in granting exemptions, had produced very unequal results; the eastern and home counties, for example, had parted with a much larger proportion of their men than the others. For a time in 1917 the calling-up of men from farms was suspended, but the spring offensive of 1918 resulted in a fresh call for 50,000 Grade 1 men from agriculture, 22,000 being actually called up. Meanwhile, however, the War Office rendered great assistance by the release of men on home service for short periods when the call for labour was greatest. In the spring of 1917, 21,000 ploughmen were lent for two months, together with an equal number of other men with some experience of the land or of horses, and these men did much to render possible the first increase of tillage land. Though 18,000 of these men in Category A had to be returned to the army in May 1917, almost an equal number of men on home service were released for the harvest of that year. Other men were furnished by the military authorities during the autumn and winter, until in the spring of 1918 there were about 62,000 men working upon the land though nominally engaged on military service.

**Assistance was also obtained from enemy prisoners-of-war. Early in 1918 prisoners at work in France, who were skilled ploughmen and had other agricultural experience, were brought across and established in camps of from 25 to 40 for work upon farms throughout England. The first prejudice against the employment of these men was soon dispelled as their skill and willingness to work became apparent, and eventually a certain number were even allowed to be housed upon farms without guards. As a rule these men were employed upon the Department's ploughing contracts or drainage operations, or other work that would absorb a gang of men and minimize the number of guards required. In the great majority of cases the German prisoners did excellent work and even came to be preferred by farmers to the local labour that had been left to them. Nor did any trouble arise over discipline; the tale is told of the guard who was brought back to camp helpfully drunk, supported by two of his prisoners, with a third carrying his rifle.**

Various attempts were made to recruit civilian labour permanently and for special harvesting operations, but with little success. The only valuable recruits that were obtained were the public school boys, some 4,500 to 5,000 of whom were formed into camps for the harvest and did service that was much appreciated, and again the camps of Boy Scouts, who in their turn did first-rate work for the farmers with whom their camp was placed. A certain number of "conscientious objectors" were told off for agricultural work, but the feeling against them in most rural districts was too strong to permit of their employment, and such of these men as were left in camps were discharged.

The greatest part of the accessory labour required in order to carry out the agricultural programme of 1917 and 1918, was provided by women. The supply was organized by the Women's War Agricultural Committee in the counties and by the Women's Branch of the Food Production Department. In the first place the employment for part or whole time of the women resident in the villages, who, in England at any rate, had largely ceased to work on the land, was revived, with the result that over a quarter of a million were at work in 1918 as compared with less than 100,000 before the war. Some assistance was given to these women by the supply of boots and other outfit for farm work. Considerable camps were also formed of college students for temporary labour in the harvests of 1917 and 1918, and these women did excellent service in flax-pulling and other seasonal operations. But the chief effort was to provide a mobile force of women's labour from sources that did not usually furnish farm workers, and at the beginning of 1917 the Women's Land Army was organized. The results were very encouraging in early months; indeed, something like 25% of the first 47,000 who volunteered were rejected, though by 1918 a considerable improvement in the material coming forward became manifest. Most of the women had to be trained, even if only for a few weeks, and in addition to the facilities provided by certain agricultural colleges and farm schools, over 600 special training centres were established. A minimum wage was laid down, at first 18s. and later 20s. a week, and in addition an outfit of the necessary clothes was provided. Depots also had to be established where the women who were waiting for employment or temporarily removed could be housed, and the women were eventually distributed between farm work, the Forage Department of the War Office and the Timber Supply Department. At first considerable prejudice had to be overcome on the part of farmers, and again great difficulties were experienced in assuring proper accommodation for the women on the farms, but by the winter of 1917-8 some 7,000 were at work, and the number increased to 16,000 in the harvest of 1918, until the workmanlike costume of the landswomen, with their breeches and smocks, became a familiar feature of all country life in England and Wales. On the whole these women proved of most service as milkers and in charge of stock and horses, for which many of them showed a special aptitude. Others again developed into very efficient drivers of motor tractors.

After the war and the return of the agricultural labourers on service, the demand for whole-time women's labour to a large extent disappeared. Moreover, a large proportion of the landwomen, especially the educated women, had taken on this kind of work for patriotic reasons, and had no call to the life of an agricultural labourer, so that the Women's Land Army was disbanded in 1919 and very few of the workers so recruited remained in 1918 upon the land. Undoubtedly, however, a certain number of women whose circumstances permitted were led to take up farming as a profession, and the whole movement, over and above the indispensable work it actually accomplished at a critical time, led to the diffusion through the community of a much better understanding of agriculture and rural life.

**Tractors.**—After labour, the provision of implements and especially of tractors proved the main difficulty of the Food Production Department. At the outset, in the early spring of 1917, with the immense urgency of getting land ploughed forthwith for the harvest of that year, it was necessary to buy every and any tractor available. Something under 500 were at work in three months, together with about an equal number of privately owned tractors which were controlled by the Department in order to get a maximum of work out of them. The Department engaged the ploughmen and operated the tractors, a charge being made to the farmers of 15s. to 20s. per acre for ploughing and half that rate for cultivating. Naturally the service did not pay its way; many of the tractors were far from efficient, and with the limited training that had been possible the drivers were at first unable to get a good average acreage worked per day. As experience of the various types of tractors accumulated it was decided to concentrate the main effort on the production of the Ford tractor, the specifications of which were placed by Henry Ford at the disposal of the Government. It was found possible neither to manufacture any of the British types nor to undertake the production of the Ford tractor in England, so entirely had British engineering works been turned over to the output of war material. Instead, orders were placed with Mr. Ford, and delivery began early in 1918. By the end of the year the Department was operating 4,200 tractors, despite the withdrawal of the large numbers of earlier types, and a further 3,000
had been sold to farmers from the supplies ordered by the Department. In the year 1918 650,000 ac. were ploughed and 80,-
000 ac. were cultivated by the Department's tractors, and in many districts where the means for arable farming had run low the ploughing programme could have been carried out in no other
way. Nor was it the ploughing only that was forwarded; the
difficult harvest of 1918 was in many cases only won through the
capacity of the tractor to get the binders over a large acreage
in a short time. Great as were the expenses attending the trac-
tor programme, it was justified not only by the immediate re-
sults but by the education it afforded the British farmer in the
use and value of mechanical traction, an education which might
have required a generation under peace conditions.

In addition to tractors, the Department obtained sanction
for the purchase of 30,000 horses, and formed gangs of teams
to work under the district committees in parts of the county
where the programme of ploughing-up grass land was beyond
the strength of the farmers themselves. The numbers purchased
were limited by the skilled ploughmen available to go with them,
but something like 10,000 horses were working under the orders
of the Department at the end of 1918 and an equal number had
been lent to farmers. The steam-ploughing tackle existing in
the country was also organized, and the owners engaged to keep their
machines at work not only through the winter but also overtime
and on Sundays. Facilities were given for the manufacture of
further sets of tackle, until there were 90 more at work by the
autumn of 1918. A very great share in the programme of extra
cultivation was accomplished by the energy of the steam-tackle
owners. Indeed, between their first meeting in March 1917 and
the end of that year over 1,000,000 ac. of ploughing and cultiva-
tion had been accomplished, and 25,000 ac. had been mole-
drained. The Department also purchased in America, and loaded or
sold to farmers, large numbers of other implements, the manu-
facture of which in Great Britain had been to a large extent
suspended in favour of munitions. Something like 5,000 binders,
as many harrows and proportional numbers of other implements,
including nearly 300 threshing-machines, were thus obtained by
the Department and disposed of to farmers.

Fertilizers.—The effect of two and a half years of war and the
increasing shortage of tonnage had begun to be manifest early
in 1917 in a very marked disorganization of all the sources of
supplies needed by the farmer—fertilizers, feeding-stuffs, se-
sels and twine. It was still possible to maintain supplies of potter-
and binder twine. The Food Production Department took
charge, and achieved remarkable success in both extending supplies and regulating distribution to ensure equality of treat-
ment and the saving of transport. In nearly all cases the or-
organization was carried out through the trade concerned, the
members of which formed associations and agreed to pool their
resources and limit prices. Practically the only nitrogenous
fertilizer available was sulphate of ammonia; shipping was no
longer available from Chile for nitrate of soda, of which an
earlier large Government purchase could not be met and had
eventually to be resold. Prior to the war the production of
sulphate of ammonia in the United Kingdom had exceeded
400,000 tons per annum, of which about 70% was exported,
while the home consumption for agriculture did not reach 70,000
tons, and indeed was not more than 78,000 tons in 1916. The
propaganda and distribution scheme of the Food Production Department secured the use of as much as 254,000 tons in the
year June 1917—June 1918. Basic slag was similarly dealt with,
grinding facilities were obtained, and the consumption was
increased by something like 200,000 tons. Owing to the shortage
of ship space it was impossible to maintain supplies of potter-
rock for the manufacture of superphosphate, but some allevia-
tion of the scarcity was obtained by the diversion of shipping to
North Africa, and over 750,000 tons of superphosphate were dis-
tributed for the year ending June 1918.

Thus the work of the Food Production Department did succeed in putting at the disposal of farmers in the harvest of 1918 a
substantially greater amount of fertilizers than they had been in
the habit of consuming prior to the war, and this at a time when
the sources were diminishing had no governmental stimulus
been applied and when most of the production would have gone
for export with the relatively enormous prices that were ruling
outside the United Kingdom. There has been but little recog-
nition of the amount the British farmer gained from the control
over fertilizers that was exercised from 1917 onwards.

Little need be said about the steps that were taken to ensure
the supply of seeds and other articles of agricultural consumption.
The most striking result was in the way in which the great death
of seed potatoes from the 1917 frost was met. More than 1,500,000
tons of seed potatoes were distributed in England and Wales and,
above all, the newly-formed allotments that had been so eagerly
taken up in that year were furnished with the seed potatoes they
needed. The opportunity was taken early in 1917 to enforce a
declaration of germinating capacity and purity of all seeds sold;
and this action, necessitated at the time by the scarcity of
material and the resulting commercial temptation to sell in-
ferior seed, so commanded itself both to farmers and the trade
that it was embodied in a permanent fashion in the Seeds Act of 1918.

Allotments.—In no respects perhaps was the Food Production
Department more successful in helping out supplies than in the
stimulus and assistance it gave to the creation of allotment
gardens, particularly in urban centres. The powers conferred
upon the Department by D.O.R.A., which were delegated to
town and urban district councils, enabled them to take possession
of any unoccupied land for the purpose of letting it as allotments,
and even of cultivated land with the sanction of the Agricultural
Executive Committee. These powers were freely exercised,
and perhaps an equal amount of land was made available for
allotments by voluntary agreement. Because of these private
agreements it will never be known exactly how many allotments
were provided during the war period, but over 250,000 were
added in England and Wales under the D.O.R.A. powers alone,
and so rapid was the further growth that it was estimated in 1918
that the total number of allotments had been more than doubled.

On the outskirts of all large towns the new movement was very
much in evidence in the spring of 1917; unoccupied land of all
kinds, building plots, waste land awaiting development, por-
tions of commons, even parks and recreation grounds, were being
divided up into plots of a sixteenth of an acre and hastily
prepared for growing vegetables. It was often late in the season
then, and the results were not very marked, but in the villages and
country districts, where many allotments were formed, the
movement was very striking. Allotments were formed at a
considerable distance from the centre of the village, and the
struggles of the béot-potagers became a byword. In the late sum-
mer and early autumn, allotments were formed of over 10,000
acres, and the increase was continued after the Armistice.

The number relative to the population varied considerably, but in and
about Leicester there was an allotment to every three households.

The benefit of the allotment movement to the community is
difficult to overestimate. There was in the first place the actual
increase in the food supply, which in England and Wales alone
was set at 900,000 tons of food in 1918. This home-grown supply
without doubt helped to steady prices in 1917. Again, the
growth of fresh vegetables by urban populations, who under the
prevailing conditions would have had some difficulty in buying
them, doubtless had a valuable factor in their war-time diet.

The development of allotments did contribute to keep down the
growth of deficiency diseases like scurvy and probably of tuber-
culosi, to which the food conditions of 1917–8 were favourable.
Lastly, very many people obtained a considerable relief from the
war strain by the physical exercise in the open air and the new
interests developed by their allotments. To many people the
war-time allotments revealed a deep-seated pleasure in the
cultivation of the land, which had been obscured to them by
residence in a town, and the strength of this feeling was made manifest by the widespread movement that grew up after the war for the retention and extension of the allotment gardens.

Of course, the close of the war necessarily led to the displacement of many of the allotments which had been formed on land that could only be temporarily allocated for the purpose. Much of it had only been handed over on private agreements and was resumed for building or other industrial purposes. Recreation grounds and park lands could not be permanently alienated from the enjoyment of the general public. Even land which had been occupied under the D.O.R.A. powers of the Board, and of which possession could be retained until March 23, 1923, had often to be given up because its retention would have involved enormous claims for compensation when the land was immediately required for building purposes. Widespread as was the demand for security of tenure in allotments it was impracticable either to gratify it now, or to repair the want of foresight when the great towns were growing, by making allotments at the expense of the community on land which had already acquired a building value of £1,000 an acre or upwards. It might still be possible to provide for allotments on such land while it was vacant and awaiting development, but only on condition that the occupiers would have to be prepared to move on at comparatively short notice when building became imminent. Many authorities in 1921 were exercising with considerable forethought their powers to acquire land for allotments, and were acquiring land conveniently accessible outside the zone of immediate development. Rounded many towns and cities a belt of allotment cultivation could be seen to be extending, though the cultivators might actually live at some considerable distance in the thickly populated inner area.

Incidentally the Agriculture Act of 1920 gives an allotment holder compensation for disturbance on similar lines to that enjoyed by occupiers of larger buildings. The growth of the allotment movement may be measured from a very full inquiry that was made of the numbers at the end of 1920. According to an early return in 1890 there were then 448,886 allotments in England and Wales of under one acre, to which should be added certain railway allotments estimated as 39,715 in 1886.

At the end of 1920 the numbers in England and Wales were as follows:

<table>
<thead>
<tr>
<th>Allotment holders</th>
<th>Acres</th>
</tr>
</thead>
<tbody>
<tr>
<td>Land managed by county councils under Act of 1919</td>
<td>329,417</td>
</tr>
<tr>
<td>Land entered upon by councils under D.O.R.A</td>
<td>198,299</td>
</tr>
<tr>
<td>Land occupied by council and temporarily not under D.O.R.A</td>
<td>56,456</td>
</tr>
<tr>
<td>Other land used as allotment</td>
<td>59,187</td>
</tr>
</tbody>
</table>

Total | 1,072,363 | 161,227 |

Owing to the fact that in six cases the allotment land was let to associations of allotment-holders, the gross total of holders should be increased to about 1,330,000. It should be noted that one-half in numbers and considerably more than half in acreage of the allotments in England and Wales were still provided in 1921 by private owners.

Control of Agricultural Prices.—The pressure of the war and the increasing difficulty in obtaining supplies necessitated a resort to the fixing of prices for agricultural commodities, which materially affected the business of British farmers during the critical years from the beginning of 1917. The Food Controller was appointed in Dec. 1916, and the Act under which he was appointed gave him very complete powers to fix the prices of commodities and to take over stocks, to control distribution and otherwise deal with all articles of food produced within or entering into the war.

As might be expected, considerable discussion and differences of opinion arose as to the methods to be adopted in dealing with agricultural produce. From the crudest point of view the Food Controller might be taken as the agent of the vast majority of consumers, anxious therefore to reduce prices, whereas the Departments of Agriculture would be regarded as the guardians of the interests of the agriculturists. Such an opposition of interests was, however, rarely allowed consciously to weigh. The divergences of opinion grew from the fact that the Agricultural Departments were more seized with the necessity of increasing production, and apprehensive of the way in which restrictions upon price might so interfere with the business of the farmer as to limit the total output of food. It may be useful to consider at this point the record of the control and the effect they had upon the course of production.

During the years 1917-9 control was exercised over the prices of all the main articles of agricultural produce—grain, meat, milk, cheese and butter, potatoes, eggs, fruit, certain vegetables, wool and hay, though in the two latter cases the control was exercised by the Boards of Agriculture and not the Food Controller. To summarise, the law fixed the control of prices of agricultural produce. Primarily the public have to be protected from excessive rises of price, due primarily to the scarcity and then to the speculation and repeated dealings amongst the middlemen that inevitably follow. The farmer, the prime producer, is rarely in a position to take advantage of the public need and, in the current slang, “to profiteer.” The conditions of the farmer’s business are such that he is waiting on the price that has been fixed in the open market. Most of his output consists of perishable materials which must be sold forthwith, and he is rarely united into associations that are capable of exercising any pressure to ensure a high price. The control of the prices of agricultural produce that follows scarcity is as a rule the work of the dealers between the producer and the consumer, and the farmer is but a passive recipient of the share that accrues to him through the competition of dealers for produce.

The second end to be attained in price control is the encouragement of production. It is possible to fix a price in the interests of the consumer which may be regarded as leaving a fair margin of profit to the producer, but which does not give him an inducement to increase production. The price is set below a level which would encourage the producer to make a special effort to increase his output, and to this end it is never possible to base the price upon the average cost of production. The purpose of the article is to go to the outer region of the powers of the Administration of the poorer farmers, whose skill may be inadequate or who are working under comparatively unfavourable conditions. As a consequence it follows that the prices will be such as give excessive profits to the more favourably situated producers. This is specially marked in dealing with agriculture—an industry in which the main is carried on by individuals working upon a comparatively small scale, an industry in which the processes are not standardized and for which no accounts showing the actual cost of production are very rarely available.

Considerable feeling was at times engendered against the farmers in the belief that their profit was not based on their cost but on the profits out of the public need and the restriction of supplies, but looking at the question broadly, these excessive profits accrued inevitably to the men who by their skill or their situation were capable of relatively cheap production.

From time to time attempts were made to establish systems of differential prices, according to districts. This was tried, for example, with milk, on the ground that the south-western counties could, as a rule, produce milk at a lower price than the rest of the country. Again, in 1918 differential potato prices were established by districts, according as they were regarded as adapted or otherwise to potato-growing on a large scale. Speaking generally, these differential prices proved to be comparatively ineffective and were the cause of great discontent and opposition amongst the producers. The main difficulty lies in the definition of districts within which the conditions of production are all the same, and it is obvious that uniform conditions of soil and climate. The object could only be rightly attained by the scheduling of individual farmers into different classes and that is administratively impracticable. In the case of the wheat the Government assumed control of all the flour-mills and instructed them to accept delivery of the farmers’ wheat at the fixed prices.
Where the processes of manufacture and distribution are not so simple, as in the case of wheat and wool, the method of making the Government the sole buyer of the output results in excessive ad-
morities, as has been shown by examples in the case of ag-
1918, when on Nov. 1 was taken over by the Ministry of Food. The difficulties were accentuated by the fact that the crop was a large one, and that it was both to be consumed by the men at the front and used for feeding the stock. It was not as sound as usual, so that in many cases the whole or part of the crop perished in the farmers’ clamps before it could be distributed. Under normal conditions the farmer who has potatoes of in-
fined quality can often sell his produce at a sacrifice, and he has been able to do so from time to time. He also looks the crop over from time to time and rejects potatoes that are becoming diseased and therefore dangerous to the bulk of the crop. Once, however, the crop had passed into the Gov-
and had suffered from disease, there was little that the farmer could do in care that it. The result in this case was a dispute as to the re-
ponsibility for the losses that occurred. The Ministry on the one hand, which had not had any dealings with the farmers as such, and the grower, for the crop, for which the farmer must bear the responsibility. The farmer, on the other hand, alleged that he had insisted in control over the crop that the losses were due to the Government’s delay in moving it to the consumer. When the Gov-
ments attempts to replace by a new official organization the intri-
cate machine which custom has built up for the distribution of any general article of consumption, the result is confusion and increased cost. The ‘trade’ machine may be intricate and difficult, but it has been in the habit of working and it has been shorn of waste by competition.

were. A Government does not constitute itself the sole buyer of the product, it yet follows that it must assume the control of distri-
bution as well as of prices. Under normal conditions it is only by the offer of a price above the average that any locality distant from the market will be induced to supply goods which are not usually supplied to itself the supplies that it needs. With a flat rate of price the producers will endeavour to sell as near home as possible. The near localities would thus become abundantly or even over-supplied, while those agricultural regions which must supply distant localities would have to pay the Government the control the distribution, but also it must fix prices all along the scale between the producer and the consumer. This it is not another more甚 than the demand would normally generate at the end of the scale, producers’ prices only. It was therefore found in practice necessary to fix both the price to the consumer and to the producer, and also the percentage that could be taken by each middle-
distributor. The Government could therefore work out an increased margin between the prime cost obtained by the producer and the price finally paid by the consumer, because all the intermedi-
daries between the producer and the consumer established their claim to a commission, whereas in practice some or other of them are generally cut out by competition, or have to take a lower toll than that for which they are able to make out a case.

Speaking generally, when a Government has to make a bargain, etc., that involves the interests of a trade for their services, it fails to get good terms. The accounts of the weaker producers or agents are always put forward, and the price is based upon the lowest possible terms of supply. Over-
over, the parties always deal in terms of round pennies and round shillings, whereas in normal working profit and loss is determined by eight shillings or sixteenths one way or another.

A system of control of prices in the United States results to a certain extent in the market for agricultural products. As a rule it has more than one way of disposing of his produce. For example, he may find it more profitable to turn his wheat into food for hens and sell eggs or poultry than to sell the wheat itself. He has the alternative of selling his barley crop or grinding it into meal and feeding pigs with it. His milk can be sold as such or converted into butter, cheese or veal, according to which offers the greater pro-
tect of profit. It therefore follows that for no article of agricultural produce can the price be fixed without reference to the prices ruling for other products which may from the farmer’s point of view be of more importance than the article in question. Furthermore, even when a given article is not used for feeding the stock, but grows at a constant rate, its value cannot be determined without reference to the price of other articles such as hay, corn, meat, milk and milk products. Prices should then be fixed in accordance with this scale of parity, weighting those articles which it is desired to produce in the general interest, and allowing them a rather better price than the scale of parity would indicate.

The neglect of this principle led to many difficulties and much dis-
content in particular cases. For example, in 1918 the prices at which the British farmer was called upon to sell his wheat, oats and bar-
ley were a good deal below the prices at which he could buy other

articles of cattle-food on which to feed his stock. The farmer was forbidden to use wheat and barley for stock if it was sound and fit for milling. On the other hand he could buy no feeding-stuffs so cheap as corn, although the fixed price of corn per bushel was very

worse for feeding purposes was more valuable to the farmer as stock food than the price fixed for sound corn. Inevitably this state of things could not but lead to the belief that the Government was doing itself a great deal of harm by not acting upon a certain amount of evasion of the order forbidding the use of sound corn for feeding stock. That the extent of the evasion was not greater was due to the general state of public opinion at the time, but the extent of the opinions of the Government would have removed the temptation and resulted in more corn being available for the general public. Another example may be seen in the case of butter. It takes from 2½ to 3 gallons of milk to make a pound of butter, yet the butter was sold at a price which it is argu-
ment. It was not unusual for a farmer to buy 2½ or 3 gallons of milk for 3s. 6d. per gallon. The result was the almost complete dis-
appearance of homemade butter from the market.

A still more noteworthy example of the difficulties arising from price fixation and the alternative use of products is supplied by the later dealings with milk. Prices of milk were fixed at six monthly in-
tervals from 1917 onwards and rose steadily from year to year as the shortage of labour and the cost of feeding-stuffs increased. The prices were fixed without doubt remunerative to the great majority of dairy farmers, as can be judged from the expansion of cow-keeping and the increase of abnormal milk production. When winter prices were fixed in the autumn of 1919 the public defi-
nitely revolted and the demand for milk declined all over the country. The situation was so bad that the farmers were called upon to
sell at 2s. a gallon or even higher prices, the price of butter was fixed at 2s. 6d. per pound. The result was the almost complete dis-
appearance of homemade butter from the market. Inevitably this state of things could not but lead to the belief that the Government was doing itself a great deal of harm by not acting upon a certain amount of evasion of the order forbidding the use of sound corn for feeding stock. That the extent of the evasion was not greater was due to the general state of public opinion at the time, but the extent of the opinions of the Government would have removed the temptation and resulted in more corn being available for the general public. Another example may be seen in the case of butter. It takes from 2½ to 3 gallons of milk to make a pound of butter, yet the butter was sold at a price which it is argu-
ment. It was not unusual for a farmer to buy 2½ or 3 gallons of milk for 3s. 6d. per gallon. The result was the almost complete dis-
appearance of homemade butter from the market.
to the extent of closing the markets to the sale of calves for slaughter and of forbidding the sale of veal. Though the measures had the approval of all the farmers' organizations they were systematically evaded and were wholly without effect in checking the increasing slaughter of calves. Again, the orders that forbade the use of barley and wheat for feeding stock in 1917 and 1918 were not observed whenever the farmer was in any real difficulty about getting food for animals. No farmer will see live stock starve and the agricultural conscience was salved by a consideration of the extraordinary mixtures of waste material that were being purveyed as cattle-food at higher prices than the farmer was allowed to receive for his sound wheat and barley. Again, in the rationing of the self-producer, the regulations declaring that a farmer might only retain so many of the pigs he killed at home, or so much of the poultry, milk, butter or cheese he produced, were simply ignored. It is impossible to enforce such regulations except by a system of espionage and inspection that is impossible in war-time for lack of men. Rationing was carried out most successfully in Great Britain, and the great force behind it was the public sense of its need and the feeling that it was being administered with perfect fairness and no favour. Nor was the pinch of scarcity ever severe enough to break down the general moral; the people at large did feel hungry and were irked by the restrictions in their diet, but they could carry on and were not impelled to illicit traffic in order to obtain food. But since the farmer saw no dire need he felt no particular compulsion to charge his ordinary way of living. It is not that the farmer is less patriotic than his fellow-men, but the war was far away from his countryside, and he is an individualist by temperament and habit, less subject to the crowd suggestion that draws the city dwellers into a common action, and with his accustomed routine as the most compelling factor in his psychology.

Should the occasion ever again arise it will be well to recognize that the agricultural community cannot be driven or subjected to the external control that proved successful enough with other industries; it must be organized from within to cooperate with the State. In this particular case agriculturalists felt the importance to the nation had been ignored in the early years of the war, and when the time came to regiment them in the common effort there was always a tinge of opposition in their attitude to the measures that were then forced upon them. Speaking broadly, it may be said that, whatever criticism may be passed on the working of the control of prices in the United Kingdom during the war period, whatever may have been the defects in the system that have been noted above, these faults were inherent in the nature of the task and were not products of the administration. The farming community often felt itself oppressed, the consuming public often regarded itself as exploited, individual hardships were inflicted and in other cases ill-deserved profits were lightly piled up, but the control did work and did prevent an intolerable state of war between consumers and producers. Control had to be, and one may look back upon it as a reasonably successful improvisation, characterized by the national qualities of fair play and compromise.

AICARD, JEAN F. V. (1848–1921), French poet and dramatist (see 1434), published after 1910 a collection of poems for children (1912) and Holland, Algérie (1913), as well as various volumes of war poetry, a novel Artiste des Mayons (1917), and two volumes of adventure stories, Un Bandit à la Francois, and its sequel Le fameux chasseur Caspard de Besse, both in 1919. He died in Paris May 13 1921.

AINLEY, HENRY (1879—), English actor, was born at Leeds Aug. 21 1879, and was educated for business; but a meeting with George Alexander and an engagement for a "walking-on" part turned his thoughts to the stage, and he joined F. R. Benson's touring company for two years. He then appeared at the Lyceum theatre, London, in 1900 as Gloucester in Henry V., and in 1902 at the St. James's theatre as Paolo in Stephen Hilliess's Paolo and Francesca. He played the comedian in As You Like It both at the Comedy theatre in 1906 and at His Majesty's theatre in 1907. In 1910 he appeared there again in many Shakespearean parts, and in 1914 he played Leontes and Malvolio in Granville Barker's production of The Winter's Tale and Twelfth Night at the Savoy theatre. After serving during the World War he began management at the St. James's theatre with Tolstoy's Reparation in 1919, following it up by a production of Julius Caesar early in 1920. In 1921 he played Prospero in The Tempest at the Aldwych theatre, and John Beal in Lord Dunsany's If.

AIR BOMBS.—Although the Hague declaration of Oct. 18 1907 contained a clause prohibiting, for a period extending till the next peace conference, the "discharge of projectiles and explosives from balloons or by other new methods of a similar nature," this declaration was only ratified by Great Britain, Austria-Hungary, the United States and Turkey. France, Germany, Italy, Japan, Russia and Spain did not sign it, and it was therefore regarded as "practically without force" (British official Land Warfare, 1912, p. 24). The only limiting condition of aerial bombardment was, therefore, that applying to all bombardments, viz.: The prohibition of bombardments of undefended localities. The word "undefended" was not more closely defined; and it could be, and by some far-seeing authorities was, presumed that aerial bombardment of localities would certainly figure as an element of the "next Great War."

In the article Air Defence will be found an account of the principles of defence against air bombardment, as they were evolved in the World War of 1914–18. The present article deals with the bombs themselves, as material weapons, and with their accessories.

Projectiles dropped from aircraft, officially termed "Aerial Bombs," may be classified as High Explosive Bombs (H.E. bombs), Incendiary Bombs, and Bomb Parachute Flares.

1. High Explosive Bombs.—The primary use of H.E. bombs is to destroy material of all kinds; they are also used occasionally against personnel. They are a species of common shell, but differ from gun shells as, owing to the absence of shock of discharge, their envelopes require less strength, and consequently the proportion of weight of charge to weight of projectile is higher. With regard to their striking energy, bombs and gun shells, when fired at high altitudes, are comparable; but the striking energy of low-trajectory gun shells, other things being equal, is far beyond that of bombs dropped even from an extreme height. The field of action of a bomb is not restricted, as is that of a gun shell, by its extreme range, but depends upon the flying capacity of the aircraft employed; but the ballistic conditions under which a gun is used give an accuracy of fire which, in the case of bombs dropped from aircraft, is reduced to a minimum.

High explosive bombs are classified as Light Case and Heavy Case. Light case bombs, pear-shaped receptacles of mild steel, weighing when filled from 16 lb. to 100 lb., were made in great numbers in the early years of the World War. They were all of the same type. The case was made in two parts; the heavier, the nose end, was a hemispherical casing; the body was conoidal, tapering towards the tail end and the two parts were joined by an angle steel ring. In the 65-lb. bomb, for example, the nose end was 25 in. and the body 64 in. thick. As time went on the type developed; fig. 1 shows a...
Light case bombs have practically no fragmentation and depend for effect on their charge alone. Heavy case bombs are made of sinclined or alloyed iron and are used in the heavy case bomb as shown in fig. 2. Its cast-iron body varies from .5 in. to 1 in. in thickness and it carries about 25 lbs. of 80/20 amatol. The fragmentation of these bombs is of the highest importance.

The general tube running their whole length, fitting into screwed sockets for which the bomb is tapped at nose and tail, except when the bomb, like the light case 25-lb. bomb, is used with a tail socket alone, when a tail socket alone exists. This central tube is divided into two parts by a rolled ring called the diaphragm for convenience in loading and keeping components in their place. In the heavy case 20-lb. and 50-lb. bombs, the tail of the bomb, like a light case bomb, is cut out of a solid piece of iron, but a light case bomb, to the latter is suspended in a horizontal position. At first bombs were released when horizontal; but now they are frequently suspended vertically from an eyebolt attached to the nose fuse, or screwed into the nose socket. When a bomb is thus released it turns over in flight and falls nose-first. Lifting bands of steel are sometimes used in place of lifting lugs. Four fuses, or fuses, in quadrature, are riveted to the case of all bombs about the tail end, to ensure steadiness in flight. The interiors of bombs are vanished or lacquered; they are then filled with high explosive.

The fuse, jc. 80-lb. bomb is filled with amatol. T.N.T., as the fuel of the charge, is varnished. JT.N.T., when compressed into pellets, is also used in exploders and as a source of detonation. Aminite, for its efficiency as a main charge, is used in explosive bombs. JT.N.T. is a mixture of ammonium nitrate and T.N.T.; at first it consisted of 40 parts ammonium nitrate and 60 parts T.N.T. (80/20 amatol) for a central exploder; and 20 parts T.N.T. (80/20 amatol) was the mixture adopted. Tetrone, a tetramethylenamine, known as tetryl, Composition Exploiting or C.E., when compressed into pellets is used in exploders and relays. Filaments of mercury are used for detonators.

Bomb Components.—Bomb components consist of fuses, exploders, relays, detonators and igniters. Those selected for a given purpose are chosen for the purpose. The assembly varies with the bomb and the purpose for which it is used. The fuse, and the exploder are usually used in every bomb.JT.N.T. is the material used as a main charge. JT.N.T. is decond by the action of the striker of a fuse, which explodes a cap or patch of cap composition, detonating a relay or exploder, which detonates the main charge of the bomb. Exploders are hollow cylinders of sheet brass or paper filled with compressed pellets of T.N.T. or C.E. They are provided at one or both ends with metal envelopes or sleeves for the reception of the parts of the explosion. Fuses must be attached to the bomb. Detonators are copper tubes of various sizes and are charged with from 45 gr. to 60 gr. of fulminate of mercury according to the use for which they are designed. When a bomb is fired by a striker they are closed by a cap. Igniters are a special form of fuses. Igniters are the charge which carries the charge between the cap and the a piece of match designed to cause a certain delay (up to 15 sec.) between the moment of impact of the bomb and the detonative action of the fuse. JT.N.T. may be used. The composition of the charge consists of nitrates and chlorates of potash, etc., mixed with shellac and methylated spirit.

Fuses.—Both nose and tail fuses are provided for H.E. bombs. The fuses are all on the percussion principle and are usually called direct-acting fuses (D.A. fuses). The first to be used by the British was a modification of the No. 18 gun percussion fuse made for a tapered bottle explosion of the type used in American bombs, was controlled by a collar carrying two small vanes, called arming vanes, rotated as the bomb descended, eventually swinging the collar off the striker and leaving it free to act in the same way as it would in No. 18. The main charge is detonated at the same time when the fuse body is struck. A tapered fuse hole being found an unnecessary refinement in the nose bushes of bombs, the latter were tapped cylindrically and fuses with conical or hemispherical thread were adopted. The latest development of the D.A. pistol fuse (fig. 2) was the peashaped type which was fitted at the top with a cover to which the vane is attached, and it is also a hanging eyebolt for the suspension of the bomb. At the bottom of the body the collar port for the detonator and relay and the assembly thus complete can be screwed into the nose of the bomb. In certain special nose fuses the action of the vane is utilized to screw the striker into position. Safety devices exist in all different forms of which the following is one example (fig. 2) and was originally given. (See figs. 1 and 2.) The striker at its upper end terminates in a screw upon which works a collar with vanes attached. A striker is fitted which, when collar screws off, releases the striker, which is then held in position by a spiral spring; on impact this spring is compressed and the striker is forced down upon a cap which explodes the bomb. If desired, however, a match burning a certain number of seconds may be interpolated between the cap and the charge, thus forming an igniter which secures the desired delay of action.

When a nose fuze is employed the striker is on impact driven on to a detonator which causes a practically instantaneous explosion; but all tail fuses must of necessity have a slight delay, for they only act when the bomb has been reduced considerably by meeting with some serious resistance, say, for example, in a delay of at least a quarter of a second, which delay can, as already explained, be extended up to 15 secs. by the use of igniters. It is evident, therefore, that by a nose fuze there is no chance of penetrating a target before explosion takes place; there is but a small crater formed and fragments of the bomb are thrown in a wide area. A nose fuze, therefore, is used with heavy case bombs in combinations of fuze, such as aeroplanes in transit, where crater effect is not required. With tail fuses, on the contrary, bombs falling in suitable ground conditions for explosion, producing considerable craters but scattering no fragments. Tail fuses in cooperation with light case bombs are therefore employed in the attack of railways, dumps, buildings, and for general local destruction.

In the attack of certain buildings a combination of a nose and tail fuze is adopted. The shearing pin of the former is such as not to be broken as the bomb passes through the roof, while the tail fuze has a delay which will cause an explosion inside the building. If in such a case a tail fuze is employed it is desirable, should there be any impact, the delay action might entail incomplete detonation or there might be no detonation at all. When bombs are made of cast iron and steel, they are employed.

Carriage of Bombs.—Filled bombs are transported in boxes, sockets, etc., plugged; components are packed in their own receptacles. Before the various detonators, relays, fuses, etc., which constitute the so-called 'domino system of craking', are in position, the bomb is tested in the dropping gear; when all is proved to be satisfactory the bomb is said to be 'live'; but all safety devices are kept in operation until the moment of ascent. If a machine lands with bombs unexpended, all safety devices are kept in operation until the bomb is removed from the carrier.

Sighting of Bombs.—If a machine be flown directly on a target at a constant altitude and with a known constant speed, a sighting apparatus can be employed, but the results cannot be expected. Its use depends upon the following theoretical considerations: a bomb, when released, will continue in a straight line at a constant speed and will pass over a horizontal distance before striking earth, which will depend on its velocity and the time taken to fall from the height at which the machine is flying. If then a right-angled triangle be formed with an altitude equal to the given height and a base equal to the horizontal distance passed over by the bomb, the slope of the hypotenuse will give the direction of the line of sight which must be employed. The heights and speeds provided for are a height of 10,000 ft. and a speed of 90 m, an hour; a height of 10,000 ft. and a speed of 80 m, an hour; a height of 15,000 ft. and a speed of 70 m, an hour, and a height of 20,000 ft. and a speed of 50 m, an hour. The height is calculated to be the maximum height which can be reached at the given speed and altitude being the factor. For the lower speed winds at the altitude will affect the bomb's movement. The bomb is given a sight to each of the sights, each for a given speed and height. Thus an observer using the back sight will have his line of sight so directed that when it passes through the target he will have released the bomb.

Typical Bombs.—The following are typical bombs for the purposes named:—The 20-lb. is a small heavy case bomb, capable of carriage by light machine; it is used in the attack of personnel, aerodromes, and the main body. It is of steel, its actual weight being 24 lb.; it will take a charge of 1 lb. 6 oz. of 40/60 amatol, or 4 lb. of 80/20 amatol. The 50-lb. bomb is a medium heavy case bomb for general use especially against material and can be carried by the most powerful of the present day bombs. Its maximum weight is 42 lb.; it carries a charge of 10 lb. 80/20 amatol; it is made of cast iron, 5 in. thick in the body and 3 in. thick on the nose of the bomb. The dimensions are 28 in. long by 7 in. maximum diameter. It is sometimes carried with a tail fuze, sometimes with a nose fuze sometimes horizontally when it is attached to the dropping gear by means of a steel band. The 112 lb. is a larger heavy case bomb, for the purpose of which there is no similar purpose in larger machines. The 230-lb. bomb is a large light case bomb, for the purpose of crater production in the attack of railways and buildings (see fig. 1). In addition to these types of bomb, special bombs have been designed for the purpose of giving special protection to structures designed to effect demolitions by the distribution of heavy fragments. It carried a bursting charge of 70 lb. of compressed T.N.T. and 20 lbs. built up of bulged segments of steel 1 in. thick at their thickest parts. The 180-lb. bomb is a similar type. It consists of a pear-shaped steel case varying in thickness from 9 in. to 3 in. from tail to nose, being provided with a cap of mild steel, composed of the same principle as a coiled armour-piercing projectile for a gun, and carrying a bursting charge of 20 lb. of 40/60 amatol or T.N.T.
A light case 90-lb. bomb has also been made for crater production and for use against submarines. When used in the latter capacity it has a special fuze to obtain "depth-charge" effect, a purpose for which the 65-lb. bomb was used in the early part of the World War. The actual weight of this bomb is 25 lb. and it carries 200 lb. of amatol. There is also a heavy case 550-lb. bomb, with a body of cast steel varying from -75 in. to 1.5 in. in thickness; it carries 160 lb. of 40/60 amatol. 

When developed, bombs tend to become larger; thus in a recent professional lecture (see Journal of the Royal Artillery, March 1921) a bomb of 1,650 lb. was spoken of, and even heavier types may be seen in the near future.

In British bombs of present make the following compositions are used:—Thermalloy, which consists of 50 parts magnetic oxide of iron, 27 parts aluminium and 23 parts sulphur; thermit, which consists of 76 parts magnetic oxide of iron, 22 parts aluminium and 2 parts oxygen; and Parachute, which consists of ground salt petre, to which is added ground sulphur, sulphide of antimony, black powder and powdered aluminium, mixed with powdered resin, tallow and turpentine. The special match composition for igniters in incendiary bombs is approximately 34 per cent of chlorate of potash, 30 per cent of filings, 5 per cent of powdered aluminium and nitrate of barium and 26 per cent shellac and ethyl alcohol.

The following are typical incendiary bombs:—The modified carcass bomb is made of tin plate, its overall dimensions being 193 in. long by 5 in. in maximum diameter. It is tapped at the tail for a pit: and the back of the body is made up of two half-cylinders and a circular head, the total weight of bomb and pistol being 231 pounds. There are two lifting lugs and is carried horizontal. During the loading of this bomb, care must be taken to prevent the accidental reception of the firing arrangement which consists of the pistol; the special igniter and the adapter and its attachment. The special igniter consists of a 28-bore Eley cap fitted with a copper sleeve containing a mixture of amatol and a pressure mechanism. The pistol is attached to a socket to which is attached a nozzle-ended celluloid tube loaded with 5 gr. of match composition. On preparation for action the igniter is pushed into the adapter, the latter is screwed on to the pistol which is then screwed into the bomb. The caseless incendiary bomb is made of thermalloy moulded over an iron framework; its overall dimensions are 27-8 in. by 5 in. (side of front section). The total weight of the bomb of 35 lb. of which 24 lb. compose the body and 11 lb. the fuze. The bomb is stowed either in a vertical or horizontal position, and is fired by a tail fuse and special igniter. It is fired in a similar manner to the carcass bomb, except that the caseless incendiary and adapter, a length of instantaneous fuse is placed below the nozzle of the celluloid tube.

The baby incendiary bomb consists of three parts, the body, the cartridge and the cap or cover. The body is cylindrical and of thin plate tin, but is weighted at the bottom; in the centre of this weight portion is placed a short pin or striker. A little above the latter are two suspending lugs for the cartridge, made by partially cutting out the body of the bomb, and the plate on opposite sides of the body being bent them inwards so as to form a support. The cartridge, which is of the ordinary sporting shape, has a percussion cap in the centre of the body, and after dropping through the two parallel walls of the body, it is shaped at the bottom, above which are three vanes with a circular disc on top of them. The assembled bomb weighs about 6 oz. and is about 6 in. long by 1 in. in diameter. The bomb is carried on the machine by a celluloid tube, which is attached to the body and falls with the vane cap upwards. When falling from heights of over 30 ft. the lugs on which the cartridge rests are on impact sheared or bent sufficiently to permit it to set forward on to the striker, when the cap is exploded and the cartridge case ejected and the thermite ignited simultaneously. These bombs are always used in masses, and are packed in a special carrier which allows them to fall with a considerable spread; thus, to take a particular example, the 272 bombs packed in one form of carrier would, if released at a height of 5,000 ft., cover an area of 30 yd. by 80 yards. The carrier can be dropped complete if it is desirable to get rid of the bombs speedily, as in the case of a sinking ship. Slightly adapted for planes is the Eley Page bomb, which can be distributed either by using several machines or by successive releases from a single machine. The small bombs provide a many-chance method of attack, which is not possible with the larger types, for with a few of these comparatively small bombs secured upon a combustible target and the chances are greatly against this combination being achieved. As, however, the small bomb is not so heavy as to allow the latter to disperse their gases over the target area, the chances of a successful attack are considerable. The 40-lb. incendiary and smoke bomb can be either burst on impact or be set off by time fuze when in the air for the attack of kite-balloons, etc. It is made of tin plate 0.025 in. thick and carries 30 lb. of phosphorus. Its overall dimensions are 1 ft, 10-75 in. long by 8 in. maximum diameter. It is tapped at nose and tail and has a central hole of 1 in., containing the cores and nozzles and vanes. When used for smoke production a D.A. pistol is inserted into the nose and the tail is plugged, but when an air burst is required the nose socket is plugged and a special time fuze is screwed into the tail socket. The bomb when in air spreads out a shower of burning phosphorus over an area of several hundred square yards. Lumps of phosphorus slowly burn out in falling and about half are used up in the first 2,000 ft. from the point of burst. If the latter be 3,500 ft. above the target the bomb will be practically lost. The special time fuze is a fuze which is not exploded by any movement and terminating at the end outside the dart in four flanges or vanes. The fuze was filled with incendiency composition which was fired after the fashion of a Christmas cracker. For this purpose a small percussion cap was used, which was attached near the end of the dart and in the tail vane of the bomb, to which the detonator is attached. It is a standard modus operandi.
AIR DEFENCE.—Even before aerial navigation and aviation had been developed to a practical point, the employment of aircraft in war for the attack of vulnerable places was discussed from time to time in a speculative way, and in the seven or eight years preceding the World War the types and characteristics of aircraft became so far definite that technical study could be brought to bear on the problem of defence, especially that of artillery defence. But this period of seven or eight years was short; military history could give no lead; practical experiments were almost impossible. Moreover, in the existing state of international law, liability to air attack was understood to depend not upon whether a place was vulnerable, in the sense that its destruction would impair the capacity of the nation for carrying on the war, but on whether it was “defended,” i.e., fortified in the conventional sense of the word, or at any rate held by a ground garrison against ground attack. Attention was therefore directed chiefly to the question of air attack on what according to the prevailing ideas were “military” objectives, and in view of the small numbers of aircraft then available such attacks were regarded as unlikely to affect the course of operations seriously.

In those conditions, and especially in the absence of all data based on practical experience, it is not surprising that defence against air attack was everywhere in a rudimentary state at the outset of the World War. In the war itself, on the contrary, experience, data and methods crowded upon one another from first to last, and through the clearer definition of the problems to be faced on the one hand and the constant process of trial and error on the other, it has become possible to formulate the main principles of air defence with some approach to precision.

I. General Considerations.

Air defence, as discussed in the present article, deals with the arrangements which deny to enemy aircraft access to vulnerable points. By “access” is implied the gaining of a position either directly over the objective or sufficiently close to it for the success of the attack. Amongst “vulnerable points” are included bodies of troops and their material in the field, centres of population, large magazines, arsenals, harbours, ports, docks, yards, ships and convoys at sea, big industrial centres, and the like. As with a fleet, the primary duty of the air forces is to seek out the enemy air forces and destroy them; but the problem in the air is far more difficult than on the sea, as a third dimension has to be taken into account, i.e., that of height. When we remember what difficulties have been introduced into naval war by the introduction of the submarines, it is not surprising to find difficulties in the air, opposing craft can pass at great heights both above and below, and other craft, more at speeds that are enormous relatively to any rate of movement on or under the sea and have to cope with extraordinary difficulties in detecting one another’s proximity, it will be seen that the task in front of the air forces of any nation is the most difficult of all.

It is a matter of no command of the air while the enemy disputes it. Therefore, against attacks by air, it is a logical necessity to provide ground defences, and to limit the radius of the air units allotted to cooperate with them. But though defence against attack by air, as on the ground, may be active or passive, yet to be effective it must be both. Further, the conditions under which aircraft move, by day and by night respectively, are so greatly different, that the conditions of the defence must be correspondingly varied to meet them.

It is not intended here to deal with operations launched over long distances against enemy aerodromes and depots, such being the role of the air forces alone, but solely with the local defence of areas occupied by “vulnerable points” as the kind which have been enumerated above.

The instruments of air defence are:—(a) the machine-gun on the ground; (b) the machine-gun in the aeroplane; (c) the heavier guns on the ground; (d) the searchlight, the sound locator, the observer post; (e) the aerial obstacles; (f) local protection on the ground, i.e., against bomb splinters and machine-gun fire, and camouflage.

Each of these weapons supplements a deficiency in one or more of the others; none is complete without one or more of the others acting in conjunction with it. From this it follows that, in any anti-aircraft organization, cooperation in effort can only be effected by organizing units of the air force, artillery and engineers under a single command, as in a formation of all arms in ground warfare.

The following are some of the forms which attacks by air may take:—bombing by airships, aeroplanes or seaplanes, singly or in formation; the harassing of troops on the ground or sea with machine-gun fire by aeroplanes or seaplanes, singly or in pairs; torpedoing ships at anchor, by seaplanes, probably in pairs or escorted by “scout” (i.e. air fighting) machines. To these may be added, though they only indirectly affect the problems here discussed:—photographic or visual reconnaissance, by aeroplanes or seaplanes, singly; and aerial engagements, by aeroplanes in formation on hostile patrol, i.e., ready to engage air-fighting groups of the enemy, or by aeroplanes, singly or in groups, attacking machines, the war engaged in observation duties (especially artillery observation) in connexion with ground operations.

Anti-aircraft units are concerned primarily with hostile attacks the objectives of which are on the ground or sea; the defence of objectives in the air is a secondary matter, but nevertheless important when air-force units are not at hand to undertake the duty themselves.

It may not be amiss at this stage to mention a few of the peculiarities of sound and light. Although these properties are generally known, their full importance in relation to air defence is seldom recognized by those who have little experience in anti-aircraft work. Sound travels at a certain rate of about 1,600 ft. per second. Aircraft are generally first detected by ear. By the time the sound of a machine reaches the ear, the machine making it will have moved some distance away from the spot where it made the sound. A path of sound is deflected by the different velocities of the various air currents through which it passes on its way to the ground. A machine in the air is only visible to an observer on the ground by reason of light rays reflected from the surfaces of the machine, reaching his eye in sufficient intensity to enable him to detect it. Thus a machine flying “straight into the sun” is invisible to an observer also facing the sun. A spherical or cylindrical surface reflects light chiefly in the direction from which the illumination comes; hence, in the case of a balloon or airship, the observer sees the target best when he and a searchlight are on the same side of it. A flat surface reflects light towards an observer further from the source of illumination than its own position; thus an aeroplane flying steadily in a searchlight beam is generally seen best when it is between the observer and a searchlight. It does not follow that because aircraft are invisible to observers on the ground the ground is invisible to an observer in the machine, and vice versa. The greatest difficulty is frequently experienced in gaining the correct focus for the eye, and, having gained it, to maintain that focus. This is a difficulty common to the observer both on the ground and in the air, but whilst the former has only to look upwards, the latter has in addition to look all round and below his machine. Neither has the assistance of intermediate objects by means of which the focus of the eye can be altered and held at definite stages. By day the observer in the air is deaf, by night he is deaf and blind. A searchlight shining into the sky is only visible by reason of the particles of “dust” or moisture in the path of the beam. In a perfectly clear or clean atmosphere the beam is invisible.1

1 Unusually clear atmospheric conditions with a few high clouds were responsible for popular rumours prevalent during the war in 1914-18, to the effect that a new invisible searchlight had been discovered which simply threw a disc of light far away up in the sky, and was otherwise quite invisible.
II. Conditions affecting the various Instruments of Air Defence.

(a) The machine-gun on the ground, on account of its comparatively short range, can only deal with targets flying at low heights, e.g., up to 3,000 or 4,000 feet. On the other hand, the ease with which it can be handled enables it to cope with the rapid change in angular velocity of low-flying targets in a way which the heavier guns cannot do. Low-flying machines move over their ground targets with a very rapid angular velocity, and owing to their small height they are often invisible from the ground objective until at a close range. Every unit of an army, therefore, requires anti-aircraft machine-gun equipment for its own local protection.

(b) The machine-gun mounted in the aeroplane can attack its target at close range, and, if its aeroplane is superior to the target in speed, it is in the flying and manœuvre position to maintain that attack until the combat ceases. It is therefore of great importance in air defence.

Mention has already been made of the difficulties of seeing objects other than on the ground, and of hearing; and to overcome them it usually becomes necessary to direct the pilot and observer by signal (visual or wireless) from the ground, to assist them in finding the target which has been selected for attack. Other serious handicaps to the observer in the air are the unstable platform for his gun and the difficulty of estimating the range to his target.

(c) The heavier gun on the ground acts in cooperation with the machine-gun in the air, and in substitution for it when weather conditions or other reasons prohibit the use of the aeroplane.

The gunnery problem is an extremely intricate one owing to the difficulties involved in range finding, the rates of change in angular velocity, the ease with which a target can change its height and course, and the fact that the target can only be engaged for a very limited space of time. The difficulties of the artillerist originate from the time of flight of his projectile. On the ground it is necessary to correct the shot in the unstable platform and by the noise made by the engine.

(d) The searchlight has three roles to fulfil in air defence. (1) It points out the selected target to the defending aeroplanes. At night the pilot is deaf and practically blind, and, unless he carries a searchlight in his machine, he must depend on those on the ground to show him where the target is moving. (2) It illuminates it for the artillery. The artillerist on the ground is blind, and cannot use his sights unless his target is well illuminated so that he can see it. (3) It exerts a moral effect deterrent to the attack. It is necessary to read the personal names of the night-flying pilots, and to listen to their conversations, to appreciate the great moral effect which the systematic and unhesitating use of searchlight beams has upon them when they are approaching their objectives on the ground. They know that once the searchlight succeeds in laying on them they become the target for every gun and aeroplane within reach—an experience to be avoided as far as possible.

There are peculiarities in a searchlight beam which handicap the detachment to a large degree; the principal one is the frequent inability of a man standing close to a projector to see a target in the beam from it. This is sometimes due to a general prevalence of a local mist which diffuses light in all directions in the neighbourhood of the projector, but it may also be due to the blinding effect of a secondary cone of light close to the base of the main searchlight beam, which prevents the man close to the projector from detecting the light reflected from the target. At distances, however, varying from 6 to 20 ft. to one side of the projector, the effect of this secondary cone of light is generally so slight as to cause no interference. Projectors have accordingly been provided with long control arms fitted with wheels or handles at the end, so that the man who holds them can manipulate the beam can do so with the minimum of outside assistance.

An aeroplane can, by "side slipping" or otherwise executing some unexpected manoeuvre, generally escape from a single illuminating searchlight, owing to the differences in the reflecting surfaces of an aeroplane when viewed from different angles. If, however, three beams manned by good detachments succeed in training on it, there is no possibility of escape. For the latter, although the detachments at those projectors are unaware of the fact that their beams are now useless, and may even interfere with each other—and consequently the work—of detachments nearer the target.

An incident which took place during the German airship raid on London on the night of Sept. 2-3, 1916, has been attributed to a range finder. This nature of airship N 17 was, however, eventually burned that night and fell at Cuffley, was entering the area over London from a northerly direction. London itself was lying in what looked like a lake of mist, and the searchlights, which were handling a "ring night" through the mist. Presently the airship was "picked up," and immediately from all quarters of the defences searchlights could be seen moving across it, until there may have been any number up to 20 beams shining in its direction.

The airship seemed to hesitate, and then swung round until she was steering north again. She was seen to empty one or more of her airships at some short distance of the projectors. The director of the searchlights was on the ground, and, during the few moments that he was visibility to the searchlights invited the arrival of bombs. The airship was then seen to turn and, at the same time, the director was seen to put his head in the air, and then to move it up and down, to a maximum of 100 degrees, high and low, to the beam of searchlights. The beam seems to have been turned in the direction in which the searchlight beam was kept in contact by a "layer," who gave suitable directions to the men at the projector.

During the first years of the war discussions were often heard as to the possibility of the instrument being of some use to the Germans. The searchlights were, in the first portion of the engagement, by observing each other in their work owing to the exposure to too many beams.

In the same engagement a searchlight near Kenton was quite useless owing to a dense mist surrounding it and the gun station near by. The local resident mentioned, by a ring night through the mist. Presently the airship was "picked up," and immediately from all quarters of the defences searchlights could be seen moving across it, until there may have been any number up to 20 beams shining in its direction.

There were several occasions when the director was seen to be pointing towards a certain portion of the searchlight beam, with the result that it prevented either gun or light detachment from seeing the target. During the first years of the war discussions were often heard as to the possibility of the instrument being of some use to the Germans. The searchlights were, in the first portion of the engagement, by observing each other in their work owing to the exposure to too many beams.

During the late summer and autumn of 1916 the use of searchlights in long ranges as a blind, and cannot use his sights unless his target is well illuminated so that he can see it. (3) It exerts a moral effect deterrent to the attack. It is necessary to read the personal names of the night-flying pilots, and to listen to their conversations, to appreciate the great moral effect which the systematic and unhesitating use of searchlight beams has upon them when they are approaching their objectives on the ground. They know that once the searchlight succeeds in laying on them they become the target for every gun and aeroplane within reach—an experience to be avoided as far as possible.

There are peculiarities in a searchlight beam which handicap the detachment to a large degree; the principal one is the frequent inability of a man standing close to a projector to see a target in the beam from it. This is sometimes due to a general prevalence of a local mist which diffuses light in all directions in the neighbourhood of the projector, but it may also be due to the blinding effect of a secondary cone of light close to the base of the main searchlight beam, which prevents the man close to the projector from detecting the light reflected from the target. At distances, however, varying from 6 to 20 ft. to one side of the projector, the effect of this secondary cone of light is generally so slight as to cause no interference. Projectors have accordingly been provided with long control arms fitted with wheels or handles at the end, so that the man who holds them can manipulate the beam can do so with the minimum of outside assistance.

An aeroplane can, by "side slipping" or otherwise executing some unexpected manoeuvre, generally escape from a single illuminating searchlight, owing to the differences in the reflecting surfaces of an aeroplane when viewed from different angles. The airship was then seen to turn and, at the same time, the director was seen to put his head in the air, and then to move it up and down, to a maximum of 100 degrees, high and low, to the beam of searchlights. The beam seems to have been turned in the direction in which the searchlight beam was kept in contact by a "layer," who gave suitable directions to the men at the projector.

By day the visual signal may be given by gunfire. By night it is more often made by the searchlight. For this purpose the Germans in Belgium erected large illuminated "arrow" piers, maintaining lamps in troughs of wood, designed to revolve on the roofs of concrete shelters.

1 By day the visual signal may be given by gunfire. By night it is more often made by the searchlight. For this purpose the Germans in Belgium erected large illuminated "arrow" piers, maintaining lamps in troughs of wood, designed to revolve on the roofs of concrete shelters.
A defect of this type was its inability to eliminate certain sounds which had nothing to do with aircraft, such as those from petrol tractors, motor bicycles, etc., on the ground in the neighbourhood. The solution which had to be given was to use the instrument at a searchlight near Bruges, because of the noise made by the frogs in the dikes all round it.

Another pattern of sound locator has been constructed in clairvoyant or echo (flying) machines, which uses a device involving the face of the cliff, and providing an appliance for detecting the sound waves at their point of maximum concentration, in such a way as to indicate the direction of the source of the sound. The sound waves meet a reflected object from the sound source, and in a manner that was only prevented from becoming public by the perspicacity of the local anti-aircraft commander.

The functions of the observer post, which may or may not be equipped with detector apparatus, are of great importance. The duty of the observer is to detect the passage of aircraft and report their movements to the authority controlling the air defences. On these reports depend the warnings to the civil and military authorities within the defended areas. Such duties demand considerable physical effort, as well as skill in the detection and identification of aircraft at great distances. The speed of aircraft in the attack is the factor which determines the minimum distance of the posts from the objective, and those distances may involve the disadvantage of great isolation for many posts. The necessity of good and speedy means of communication between such posts and the controlling air defence authority to which they belong is obvious. However excellent an observer's training may be, a report based solely on what he has heard must be open to doubt, and he attempt identification of the class of the aircraft in question.

The aerial obstacle consists of some form of wire impediment, hung from balloons, and intended to be such a menace to a flying machine that it will either pass beside the obstacle or, more probably, fly at a higher level than the balloons supporting it.

The Italian authorities claimed extraordinary success with the contrivances used in their defences. The French authorities were not so optimistic over the type adopted by themselves, and there is no proven case of success with the pattern used in Great Britain. The Germans at Bruges and Zeerbrugge flew kites and balloons by wires of a very high tensile strength, and one Hanley Page bombshell was shot down by one of these means. The balloons were about 15 ft. in diameter, and were used when wind power was insufficient to raise a kite. The kites were of a light and smoothly polished material, and were suspended by double lightweight copper wires. The lower ends of the wires were wound on vehicles provided with gauges, oil baths, and lightning "earths." They were managed by a few small boys, pressed into the German service at the rate of a few francs. It was estimated to attach a small charge of explo- sive sufficient to destroy an aeroplane wing, to a revolving vane by a length of fine cord. The charge was fitted with suitable concussion firing arrangements. The vane was attached for the purpose of marking the track of the air. Once the vane and vane were neatly packed together so that considerable numbers could be carried in a box provided with a simple release. The pro-

1 A curious incident occurred during an air-raid alarm in London during the war. To the astonishment of the detachments one complete set of balloons came down with unexpected suddenness, all being deflated by the rupture of their ripping panels. On examination, it was found that moisture had condensed on the ripping ropes and the lifting gases, thus causing the balloon to become as light as a man's forearm. The weight had gradually increased on all with remarkable regularity until the ripping point was reached, when each balloon in the series was deflated almost simultaneously. There was a heavy mist that night, and the temperature at the ground level was above freezing-point.
III. Forms of Attack.

The effects of bombing are moral and material. There is no doubt that the moral effect is far greater than the material—particularly in thinly populated districts where self-control, as a general rule, is hardly lacking in the population to a greater degree than amongst armed forces in the field. No result decisive to a campaign has been brought about by a raid of any kind of itself alone. This fact will probably be true of aircraft bombing operations, provided that a country has taken suitable precautions in peace against the chance of an overwhelming attack at the very outbreak of war.

Written evidence was found during the war of the nervous apprehension reigning in a certain German town after the evacuation of the local factories by Independent Force, R.A.F. had been operating for a comparatively short time. One of the inhabitants described a night of terror in which Allied aeroplanes had come in the early night and dropped their bombs and gone away. He had the inhabitants come out of their shelters to go to bed than they were again summoned under cover, and the bomb dropping was repeated. Again they went to bed, and again they had to come out. As a matter of fact one solitary Allied aeroplane paid a single visit to the town that night; the rest of the raid was purely imaginary, and the result of demoralization! Over another large town six long air raids took place during eight nights. One effect was that the clothing output from that district was temporarily reduced by 80%—a serious matter for the army, as a large proportion of the force was depending on the district for its clothing.

Bombing operations over disciplined forces in the field constitute on the whole a form of annoyance rather than a potential danger, provided that store and ammunition depots are so designed as to be separated from each other, and subdivided within themselves, in such a way that a fire arising in one section may be properly isolated and prevented from spreading to its neighbours. Interference with movements of troops and stores by rail can be, and has been, caused by low-flying bombarding machines.

Airship Attack.—Airships form targets of great size, and, if filled with inflammable gas—as were those of the Central Empires during the war—are objects of considerable danger to their crews. If and when a suitable non-inflammable gas is discovered which can be used cheaply for non-military purposes, the airship will become a serious factor in air-defence considerations. It possesses greater endurance, radius of action, carrying capacity, accommodation, and facilities for observation than "heavier-than-air" machines. Meteorological conditions, however, will always militate more against the free use of airships than of aeroplanes, which possess higher powers of manoeuvre and performance.

During the war bombing operations by airships were not intentionally undertaken by the Germans over land targets by day, but ships at sea were frequently made the objects of such attention between dusk and dawn. Airships intending to attack land objectives in the British Isles were used to leave their sheds by day, and make their landfall, while still over the North Sea. There they would wait until it was dark enough to cross the coastline without prospect of serious interference, and make for their various objectives—as a rule more or less independently, but sometimes in pairs. The return journeys were made independently.

It has been held that at night it is hardly necessary to attack with more than one airship at a time, but there is no doubt whatever that simultaneous attacks by two or more airships on the same or similar objects are of considerable value, and the results of some of the raids can only be explained by assuming that airships were used together.

The German raid on London during the night of Sept. 28-29, 1916 affords a notable instance of airships setting out to attack in pairs, but failing to carry out their intention. L31 and L32 sailed on the task in company and reached Dungeness together. Thence L31 stationed round a boat and set her men ashore, and L32 passed over London at high speed, and eventually won through. Her consort hesitated, and was lost. L31 passed over Hurley and Croydon, and dropped a very brilliant flare as she turned on a northerly course. This undoubtedly had the effect of distracting the ground defences from herself; for she was securely seen as she passed over the metropolis, and bombarded it heavily without damage to herself. She reached home in safety.

The parachutes which follow are applicable also in the main to seaplanes. Nevertheless the typical differences between the two types are so great that many will doubtless be unable to picture them without the help of the illustrations. The principal difference is that seaplanes require no landing ground or special arrangements for launching and landing ships. They can take to the air from any water, or, at least, from water of such a kind that it does not freeze. On the other hand they find difficulty in "taking off" in rough water. Their powers of manoeuvre are, however, comparatively limited. They come chiefly into the consideration of coastal air defence, owing to the necessity they are under of landing on water. But amphibious machines are certain developments of the near future, and wide canals such as that between Bruges and Zeelbrugge have served as landing places and enabled seaplanes to operate from a point inland and sail from interference from the sea.
at a serious disadvantage if attacked by enemy aircraft, as their defences are in a comparatively small area at a fairly low height. To defend each of such machines by an aerial escort would absorb too great a number of fighting aircraft, and so the duty falls most frequently on the anti aircraft artillery and such machines as are available. Air defence work—properly planned—can be directed to the spot in sufficient time to provide the protection required.

IV. The Defence in General

It will now be realized that air defence is required both in the actual theatre of active operations in the face of the enemy, and in areas far to the rear of the fighting line, so long as the enemy has machines capable of reaching those distant points and returning again from them. Bombing attacks may be met anywhere, i.e., in both the forward area of ground operations—the "Front"—and also in store depots, bases, ports, and large cities far removed from them.

In flying machines with bombs or machine-guns may be encountered far in rear of the "fighting line," but principally in or near it and over the communications immediately behind it; so that, as a broad general rule, the nearer the "line" the greater will be the proportion of low-flying targets, and vice versa. Torpedo-carrying machines will be met with over the sea; and photography machines anywhere between the "line" and points far in rear of it on the lines of communications.

In order to place defending aeroplanes in positions favourable for engaging their targets, it is necessary to obtain information of the attack in sufficient time. This leads to two great essentials in any scheme of air defence, namely:—(a) intelligence, and (b) communications.

(a) Intelligence can be treated under three headings:—

(i) during peace, and before the beginning of an attack in war;
(ii) during an attack; and
(iii) immediately after an attack.

Intelligence before the beginning of an attack includes information obtained during peace of all the resources of a possible enemy; his preparations and probable intentions; with the numbers, details and performances of his machines both civil and military. On such information will the whole scheme of air defence of a country and its forces in the field depend. In peace such information can be collected, compiled, and assimilated in a careful and comparatively slow manner. But directly a state of war arises, speed in the collection and transmission of that intelligence to those whom it most concerns, i.e., the commanders, becomes the determining factor. The authority responsible for the collection of that information has to add comparatively suddenly to his ordinary peace-time duties that of rapidly tracing the movements of both hostile and friendly aircraft, as by no other method can an officer check information sent to him by his observers. Only on the efficiency of the preparations made for the use of telephone, telegraph, and other signals can he hope to issue the warnings which will be required by the population to enable them to take cover during a raid. The state of war may even be heralded by the air attack itself, and there may only be a matter of a few hours for the transition from "intelligence duties during peace" and before an attack" to "intelligence during an attack." It will be best to consider a concrete example, which will show perhaps more than anything else the necessity for speed.

Take an imaginary city with an average radius of 12 m., with its inhabitants sitting out of the reach of bombs. West of the city a certain number of aeroplanes, capable of returning hit and run attacks, are perched on top of the mountains. If the aeroplanes were to attack the city a number of aeroplanes, the city reports a number of aeroplanes as having been heard passing high overhead, going west at an estimated ground speed of 100 m. per hour. The message, which is probably sent "in clear," is picked up by some coastguard station, which sends it to the local senior naval officer and so to the military garrison commander near at hand. These officers, after digesting the report, and confirming it if possible, send it on through their respective headquarters to the central organ of the system. Then it goes to the railways, to the police, and to air defence headquarters, who call the rumour to the attention of the citizenry, and to the police, and to air defence headquarters, who give the alarm to the rural towns, to the civil population, and to the squadrons of bombs, guns, and maintaining aircraft, respectively.

The defending squadrons will probably be situated from 15 to 20 m. from the centre of the city, i.e., about 40 to 45 m. from the source of the report. At the squadron aerodromes the pilots, who are waiting ready to start up the machines, "taxi" over the aerodrome, and then "take off" and begin to climb to predetermined heights, as the real height of the attack cannot be known at the moment.

A little time-table will show the time probably left to them to get up to, say, 10,000 feet.

| Time taken by attack to travel 40 to 45 m. say | 27 minutes |
| Ship to shore | 5 |
| Coastguard to local H.Q. | 2 |
| Local H.Q. to main H.Q. | 2 |
| Main H.Q. to Air Defence H.Q. | 1 |
| Air Defence H.Q. to units | 1 |
| Starting up machines, "taxi-ing" and taking off | 5 |

Total (say) 17

Leaving the machines to get their heights in

As soon as the attack enters the area in which anti-aircraft posts exist, each of such posts within sight or earshot of the machine becomes a potential source of information. It remains then for the commander of the air defences to organize his system of speedy intelligence within his own command, which can be supplemented by reports collected from police and railways, which may or may not assist in checking the reports received from the defence posts themselves. This system continues its work until such time as the attack withdraws to a point outside its boundaries, when intelligence is again required from outside sources until it is certain that the engagement is over.

Directly after the attack it becomes of importance immediately to check the commander's ideas of the battle, to supplement them with local details of what actually happened, and to compile as complete an account as possible of the operations. But Nature and numbers of aircraft employed on each side; routes followed by attack and defence; casualties to personnel and material; number and nature of bombs dropped; expenditure of ammunition; size, speed, and manoeuvres of enemy machines; new features of machines, if any; efficacy of communications; weather conditions, etc. This report is of high importance and may enable a commander, if it is compiled and issued rapidly, to dispose his forces afresh in sufficient time should features in the attack show this to be necessary.

This connexion, it is important to note certain peculiarities of air-defence information. A report on the position of aircraft in movement is incorrect the instant after the observation is made, unless the time of the observation is given. The value of the report decreases with every moment that elapses after the observation. To be of value at all it must specify whether the aircraft was seen or only heard; if the former, whether friendly or hostile; and the time of the observation. To be of real value, it should contain data as to the direction of flight, the number and type of the machines and their height. One of the outstanding curiosities of the air raids over England was the remarkable accuracy of the reports rendered by eyewitnesses which were received by the various local authorities. To men who have been in the services the hypothesis that the man "on the spot" knows what is going on and therefore knows best what should be done, will be familiar. The history of anti-aircraft operations during the war abounds with instances showing the fallacy of that hypothesis.

During the aeroplane raid of June 1917, over Sheerness, Gravesend, Wrotham, and Folkestone, two independent reports were received of an airship approaching London in broad daylight from
a point between Gravesend and Wrotham. They were the only intimations of any airship being present. One of the reports came from an officer, and one from a searchlight detachment; all had been used to seeing airships at night and knew what they were like. They were closely examined and there to no doubt that they were mistaken, but none of them was ever shaken in his conviction that he had seen an airship.

The airship was detected at Hyde Park were threatened by an angry crowd one afternoon in June 1917, because they would not open fire on a British machine flying high overhead. An air raid was actually in progress over East Kent at the time.

The bombs were reported one night as dropping in places up and down the eastern-ports of Lincolnshire and Yorkshire, but a duty officer sitting over a map in London could only trace the noises to echoes of a serious explosion which had taken place a short time before the Lincoln and Yorkshire, and to be assured the responsibility of declaring to give an alarm; he was right.

An airship was reported as visible and audible over the scene of the great Silvertown explosion in east London within a few minutes after the last explosion there had taken place: it was identified with a curious wisp of smoke which many spectators had noticed in the glare of the flames. The sound of the engines was purely imaginary. Thin long clouds were frequently reported as airships on moonlight nights.

These few examples will show the unreliability of reports concerning airships, and bring in prominence the enormous responsibility of searchlighters and searchlight officers, who, sitting miles away from the scene in a closed room, has to decide whether an observer really has seen or heard what he has said he did.

In making observations on the movements of large cylindrical airships, a common cause of error is due to the lack of an appreciation of the effect of perspective. An airship travelling horizontally and straight away from an observer may give the impression of falling vertically, nose downwards. An obliquely approaching airship may appear to be gaining height, and vice versa, although travelling at a constant height. Further, the observer on the ground is unable to assist himself by comparison of the size of the machine with other objects, the sizes of which may be familiar, placed at gradually increasing distances from him, and between himself and the airship.

The vagaries of the path of sound emanating from aircraft have proved extraordinarily deceptive. An officer accustomed to living in a shelter on a roof in the heart of London was able, while inside the hut, to detect sounds of aircraft which were quite inaudible to him when he was outside it. Local slopes and wooded country lead to confusion in the intensity and direction of the source of sound.

During the raid of May 23rd-24th 1917 on the London area, airships were reported independently as "almost overhead" by three experienced anti-aircraft detachments in the neighbourhood of Hoddesdon and Hatfield, though no airship came nearer than within 25 m. of them, and the reports were probably due to peculiar and distant formations which lay over the London area at the time. During the same engagement, bombs dropped between Braintree and The Wash were reported as clearly audible from Putney Heath and south-west of it.

In a civilized country, warning of an approaching attack by air is required by both civil and military populations. Here again the organization must be based on "areas." It is not possible to decide beforehand the objective of attack by air, but it is possible to fix the degree of probability of attack on the different vulnerable points in any country. In each of such vulnerable points certain precautions are necessary, such as the evacuation of the workers from an explosive factory, the dousing of bright lights, or the control of railway traffic. These precautionary measures take time to bring into force but it is nevertheless desirable to bring them into force only at the very last moment, in order not to delay output or cause unnecessary alarm and congestion. It becomes necessary therefore to keep a quick and careful record of the enemy aircraft movements, to divide up the country into "warning districts," and to provide a good system of distributing the warnings.

The movements of the attack are recorded by the "intelligence" system. The sizes of the warning districts depend on the speed with which the attack may move, as well as on the time required to bring the precautionary measures into force. The system of distributing the warnings will rest with those civil authorities who act as guardians of the public safety, who will probably use the civil telephone system.

Warnings and orders will normally be divided into: (a) preliminary warnings as to the approach to the area of an attack; (b) definite military orders as soon as the attack has entered the area; (c) messages cancelling (a) and (b).

As regards railways, special arrangements are necessary. Complete stoppage of railway traffic creates such disorganization that weeks may be taken to recover from it. Failure of train service causes the assembly of huge crowds of would-be passengers at railway stations, and so the formation of "vulnerable points" in which a single bomb would cause immense destruction of life. The dislocation of the traffic suspends the punctual delivery of goods, and upsets transport arrangements throughout the whole country traversed by the railway system, as well as in the parts of the country that are connected with that traffic. There is therefore no longer in hands of the railway authorities, but is advised by the military authorities of the assistance the system may afford to hostile aircraft under certain circumstances. Both the railway and military authorities render each other mutual assistance in the interchange of information regarding the progress of an attack by air.

Signals may be sent by wire, wireless, and visual means. Means of communication are required between:-

</thead>
<tbody>
<tr>
<td></td>
<td>Points on land</td>
<td>ships on the sea</td>
</tr>
</tbody>
</table>

Signal by wire is only possible between stationary points, i.e., those on land or the shore and anchored vessels at anchor. Visual signalling between machines in the air and points on the ground is frequently by atmospheric conditions, but also by the necessity of concealing the position of machines in the air. As between points on the surface of the earth, intervening ground features as well as atmospheric conditions may interfere.

In order to minimize the inevitable congestion which arises where the same wire circuit is used for the dual purpose of collecting and distributing information, independent methods must be provided for the two processes wherever this can be arranged. As far as possible information should be collected by wire circuits, but after verification it may be distributed by any method available. Wireless is of value between machines in the air, and enables formation commanders to communicate with each other, and with the machines. Wireless facilities are also required to enable machines to check their navigation reckonings, and to assist in them in locating landing grounds, particularly when fog or cloud prevail. For the communication of intelligence before the latter has been thoroughly investigated its use is a source of danger, owing to the ease with which wireless messages can be "picked up" and to the large proportion of inaccuracies to be found in messages concerning aircraft.

These broad principles apply to all "back" areas; but in "forefront" areas where shell fire renders the maintenance of wire circuits almost impossible, resort to wireless alone may be necessary, if the passage of aircraft intelligence is essential in the area affected. That the highest standard of accuracy and rapidity is required to make the service of communication efficient for crises in which minutes are precious goes without saying.

V. The Application of the Various Instruments of Defence.

In order always to be as economical as possible, air defences must not be disposed too far from the area they are intended to defend. As the attack can come from any direction, they must be disposed all round that area. To dispose ground defences along the boundary of a state with aeroplanes on patrol on either side of them, in order to keep the invader out of the state
at the outset, is to be "strong everywhere," and consequently "strong nowhere." Such a policy involves dispersion of available strength over unimportant localities, reduction of control, loss of cohesion in effort, extravagance, and the achievement of a minimum of efficiency. The close defence of the localities which are important to the state is the only sound policy.

For the defence to be effective, the attack must be met and defeated at the right height and outside the line from which it can achieve its object. Such at least must be the aim of the defence, however difficult it may be of achievement. That is to say, the defence must be outside the objective of the attack. This necessarily plunges the matter at once into difficulties with what is known in the army as the "chain of command." An army works by definite boundaries shown by real or imaginary lines on the ground. The air knows no boundaries. It follows, therefore, that those units of air defence formations which are tied to the ground must be sited and organized for purposes of command with no regard to those imaginary territorial boundaries necessary to the ordinary army of the ground, and solely with regard to the whole area in which the vulnerable point or points are situated.

In one respect the sea has an important bearing on the nature of aeroplane attacks. The risk of being shot down on the return journey is less, because it is possible to have a circle of lights set up round the aerodrome to illuminate the aeroplane, and a searchlight at the aerodrome can still be seen over a distance of many miles. The problem of defence fixes itself on the land. As has been shown, this involves the need for searchlights. Searchlights may be placed round aerodromes and on coastal points, to illuminate ships and coastal towns.

Some typical instances of the use of the various instruments of defence may now be considered. The defence has to provide against attacks both by day and by night. By day the instruments of defence and their adjuncts are: the machine-gun in the air, the heavy gun on the ground, the sound locator, and the observer post. By night the machine-gun in the air must be manned by a crew specially trained in night fighting, and in addition there is the searchlight. By day and by night the object of the defences is to break up the enemy attack and destroy it in detail. By day the massed attack must be broken up by gunfire before the aeroplanes on the defensive are launched against it; this entails guns outside the defensive aeroplane patrols, which again are limited by the scale of the defence. For the operation of the aeroplanes (i.e., in rear of them) more guns again are required to repel such of the attackers as succeed in penetrating the aeroplane patrol area. And lastly, throughout the area of the vulnerable point itself, provision must be made for attacking by gunfire any hostile machine which may succeed in penetrating so far.

The attack will probably be audible and visible throughout the greater part of its course. In certain conditions of thick cloud or haze it may be invisible from the ground, but this fact, though increasing the difficulties, does not alter the disposition of the defences.

By night the attack is broken up in an entirely different manner. Both attacking and defending machines being in darkness, the attack is, as it were, reconnoitred by the searchlight, and the targets selected by the latter are isolated for engagement by the apparently simple process of keeping them illuminated. Unless the searchlight succeeds in their object, the attack is invisible.

It is not possible as a rule to illuminate several targets in a searchlight beam simultaneously, although during the war as many as five have been held in the beam simultaneously for a few minutes; nor is it likely that any method of illuminating a formation of, say, 22 machines simultaneously, for any length of time, would be practicable. The outer ring of guns, therefore, would normally remain inactive by night unless the absence of a defending aeroplane gives an opportunity for a gun to engage an enemy target.

By day and by night the aeroplane in defence can only move a certain maximum distance on patrol without running the risk of allowing an attack to slip past in rear of it; the aeroplane also requires a certain minimum distance on one side or other of its patrol line in which to manoeuvre and bring its enemy to battle. Suppose for the purposes of illustration these measurements be taken at 15 and 10 m. respectively. The aeroplane patrol area, and the battle and pursuit area, must be kept as clear as possible of gunfire areas and areas containing vulnerable points of any size.

The width of the gunfire area will depend on the probable height at which the attack is delivered. Assuming that the nearer aeroplane is 10,000 ft. and that the gun can command a horizontal range of three miles at that height, the belts of gunfire may be taken at six miles in width. Observer posts must be between 70 to 100 m. away, as has been shown, in order to gain time for the defences to get into position, if they are to meet the attack as it comes in and not bring it to account merely as it is returning home.

In the case of a vulnerable area represented by a circle of a radius of 5 m., the area immediately outside that will be a belt for gunfire from 3 to 4 m. in width; the next a belt of 10 m. for the aeroplane battle and pursuit area; then one of 6 m. for the outer gunfire area; and a final belt from 45 to 75 m. wide covered with a network of observer posts, each of which can be from 10 to 15 m. from each other. This arrangement provides for the problem of defence by day.

By night it is necessary to consider the disposition of the searchlights, and it will have been seen that one of their functions is to indicate the approximate position of attacking aircraft. To be of any value they must be able to do this throughout the vulnerable area, the adjacent gunfire area, the battle and patrol area, and for a sufficient distance outside the latter (say 4 to 5 m.) to enable the aeroplanes patrolling in defence to move into position to meet the attack. This gives the total area through which the searchlights must be disposed, the projectors being at the angles of triangles whose sides measure approximately 2,500 to 3,000 yards. Owing to accidents on the ground, trees, houses, railway stations and the like, the actual distribution of searchlights throughout the area often appears to be indiscriminate; it is inadvisable as a rule to place a searchlight nearer than from 200 to 500 yd. from a gun. Again, by night, the difficulties of determining the height of the attack are so great, that it becomes necessary to dispose the aeroplanes in defence at different heights. Assuming this difference to be 1,000 ft., a certain number of machines will be disposed on each level, with the highest at about 8,000 ft.; the highest will be at 12,000 ft. The degree of endurance to be expected of a pilot flying on patrol at night may not exceed a tour of two hours in the air.

These data, combined with a knowledge of the average lengths of the summer and winter nights, will be sufficient to give some indication of the minimum numbers of machines and pilots required in the problem of night defence. The number by day is also affected by the probable frequency and size of the attacks.

It will now be easy to realize the enormous scale of defences required if any appreciable degree of efficiency is to be attained. A simple diagram will illustrate this general disposition of defences.

Few "vulnerable points" are as symmetrical as those indicated in these diagrams, but the principle illustrated can be applied to areas of almost any shape.
AIR DEFENCE

All that can be done is to increase the intensity of the gunfire belt to seaward, and to provide aircraft detector posts and instruments with a directional value in azimuth rather than vertically. The latter serve as a partial substitute for the observer cordon by giving somewhat distant warning of the approach of aircraft.

The defence of towns and ports separated from enemy territory by sea alone thus requires maintenance in a state of instant readiness for action, and so calls for a greater complement of personnel than would be the case in defences situated inland.

The areas on either side of the dividing "line" between opposing forces in the field, up to a distance of some miles from the dividing line, are generally described as being the "forward" areas. The areas behind the forward areas were usually termed "back" areas; the latter term, however, was not generally taken to refer to places outside the "theatre of war," though from the point of view of aircraft action it was just as applicable.

In "forward" areas vulnerable points in the nature of men, guns, animals, and ammunition stores are numerous, but as a rule well distributed. In "back" areas they all tend to greater concentration. Protection is therefore more easily afforded in the former than in the latter, and so the better targets for bombing machines will be found as a rule in "back" areas.

The nearer the "line" the more intense will become the fire of hostile ground artillery; this precludes the free use of searchlights nearer than about 5,000 yd. from the "line," and necessitates the distribution of anti-aircraft artillery in smaller fire units than is possible. It is a greater risk to the enemy.

Targets will be far more numerous in the forward area than in rear of it, throwing much more work on the anti-aircraft artillery situated near the line.

Applying the principle, as illustrated in the figures, to the problem in the field, a distortion of the diagram results, as in the cases of coastal towns. The outer ring of guns (fig. 1) is formed by the guns along the line and the Bristol Channel as a spear area to be provided with defences under one command. Therefore this whole area will, for purposes of air defence, have an organization independent of all those ordinary commands and military formations whose activities are limited by conventional lines on a map.

The same line of reasoning applies to forces in the field with their "forward" areas, lines of communication, and bases; and necessitates the problem of air defence being considered with reference to the whole area of active operations, and not merely to that of all the independent vulnerable points within it.

The principle illustrated in the diagram will be found applicable to most cases, provided that consideration is given to the relative urgency of demands for gun and aeroplane defence combined, and of aeroplane defence alone. For the civil population, whilst applauding the courage and success of the airman, is ever apt to mingle with its praise a demand for a gun. A gun is tangible and comforting; it can be seen and heard; and so it produces on the population a moral effect which may be more than counterbalanced by the interference it may cause to the defending airmen.

An instance, already alluded to, in which the principle requires modification, is that of coastal towns and harbours, few of which can be situated geometrically so as to admit of the all-round disposition of defences illustrated. Here the sea intervenes to cut off observer posts, searchlights, and guns, in addition to restricting the area of manoeuvre for the defending aeroplanes by night. This inroad into the defences offers the enemy an avenue of approach, and necessitates considerable strengthening of the batteries within the range of and covering the sea in the neighbourhood. A certain amount of defence may be afforded from vessels afloat, but reliance cannot be placed on them for anything more than a temporary assistance, as they may only be present for uncertain periods.

VI. Some Possibilities of the Future.

Some limit to the speed of aircraft and the height at which they can fly must be assumed, and, as far as the possibilities can at present be imagined, heights up to 30,000 ft. and speeds of 200 m. per hour, together with powers of long endurance in the air, may come within the range of practicability during the next 20 years or so. A successful development of the helicopter would bring about a great change in the power of manoeuvre of aircraft, and enormously increase the difficulties of the defence. Detection of approaching aircraft will be required diligence of the operators of the machinery; their destruction by fire will be hampered by the introduction of metal protection. Wireless aids to navigation will decrease the difficulties of the pilot in thick weather, improvements in the landing power and stability of machines will increase their immunity from storms; and all these conditions will call for a greater state of readiness in the defence. On the other hand, improvements in artillery will be necessary, and will follow as a natural consequence. Inventions for the detection of the locus of the source of sound will facilitate the accuracy of searchlight work. These factors, in their turn, will impose greater caution on the attack and give greater confidence to pilots patrolling in defence. Aeroplanes now used in defence will in the course of years become less localized in their work, and will develop a tendency to operate more and more like battle-fleets at sea. Such aerial fleets operating from their bases will be likely to carry their own armaments and searchlights, and to be accompanied by what we may call their "destroyer flights," which will assist them to seek out and find the enemy themselves.

The improvements which will produce this tendency will only mature gradually, and danger will lie in the endeavour of the ground forces to service the airmen in the protection of air raids before being in a position to do so. There must be a long transition period during which cooperation between air and ground units must be the strongest link in the chain of
AIRD, SIR JOHN—AIR RAIDS

Defence. Only in proportion as the air services become of a more stabilized nature, and anti-aircraft artillery improves, will the need for close cooperation diminish; it will never entirely disappear. The inability of the British navy to prevent short raids on the East Coast towns of Great Britain during the World War must not be forgotten; in like case, no country will ever be able to make good a defence against aerial raiding attack by aircraft alone. Consequently a nation must guard against exposure in the transition period to dangers which the air services or ground services of themselves alone cannot avert. Local ground defences will always be a necessity; and reliance on them will become greater owing to the many and devious paths of approach open to the enemy taken in conjunction with the reluctance of a nation to expend the huge sums necessary to provide aircraft to watch them all.

Every disease produces its own remedy; and in the end only the highest degree of excellence attainable by the arms of defence on the ground, acting independently of the units in the air, will procure the maximum of immunity for vulnerable points.

(M. St. L. S.)

AIRD, SIR JOHN, 1ST. BART. (1833-1911), British engineer, was born in London Dec. 3 1833, the only child of John Aird, contractor for gas and water plant. He joined his father's business at 18, and was entrusted with the removal of the Crystal Palace buildings from Hyde Park and their reerection at Sydenham. He took part in many enterprises at home and abroad, such as the Hampton and Sinines reservoirs, the waterworks of Amsterdam, Copenhagen, Moscow, Bahia, Pará, Calcutta, Simla and Berlin, and later (in the joint firm of Lucas & Aird, afterwards John Aird & Co.) the St. John's Wood railway, the Hull & Barnsley railway and docks, the W. Highland railway and the great Assuan dam across the Nile. He represented N. Paddington in Parliament as a Unionist from 1887 to 1905, and was its first mayor in 1900. In 1901 he was created a baronet. He made a fine collection of pictures by British painters, the illustrated catalogue to which was printed in 1884. He died at Beaconsfield, Bucks, Jan. 6 1911.

AIR FORCES—SEE FLYING CORPS.

AIR RAIDS.—Air-raiding by airships, and still more by aeroplanes, was carried out during the World War in most of its geographical areas. German bombers were particularly active in France, and many towns near the Rhine suffered severely in later times from the aeroplanes of the British Independent Air Force. But nowhere can the history of the continual see-saw of success between raiding and air defence during the war be studied better than in the German raids carried out over England in general and London in particular. Their story during 1914-5, 1916, 1917 and 1918 will be given here.

1914-5.—Directly Great Britain came into the war, the German High Command began to encourage their public with prophecies of the havoc the Zeppelins were about to work in England. Disillusionment came quickly. The experience of some of the smaller airships, attempting to work by day over Belgium and Lorraine, was by no means encouraging. Three were destroyed at once, and it became evident that for airships to fly low in daylight over enemy territory was to invite certain disaster. Hence it was that, although reconnaissances over the North Sea were made, Germany was not again attacked by airships, the first actual attacks were made by aeroplanes.

In Dec. 1914 a couple of bombs were dropped in the sea off Dover, and three days later, on Dec. 24, the first German projectile hit English soil. A small bomb fell near the Castle at Dover and broke some glass. Both these aeroplane attacks were in the nature of a surprise, and the defences, such as they were in those days, could take no action. On the following day a seaplane dropped a few bombs at Sheerness, without effect. This time both the ground and aerial defences took action; but British aeroplanes came in for most of the anti-aircraft fire from the ground. A few half-hearted attacks by aeroplanes and seaplanes made during 1915 were ineffective, except that two women were killed at Margate in September.

The baron honours of the first attacks having fallen to the aeroplane, it was left to the lighter-than-air machines to cause the first serious damage and loss. In the evening of Jan. 19 1915, two naval airships approached the coast of the eastern counties between Yarmouth and Cromer. They separated and dropped bombs on both towns. One of the raiders went out to sea again at once; the other, handled with greater boldness, proceeded to King's Lynn, dropping bombs as it went. Four people were killed, including two women, and the material damage was estimated at £7,000 or £8,000.

On April 14 the redoubtable Mathy, boldest and ablest of all German air commanders, began his activities over England. Commanding L4, a new and improved type of naval airship, he made a considerable tour over the North. On this occasion he was not particularly successful, most of the bombs falling harmlessly in open country. At Walsall, however, he succeeded in singeing the hair of a woman who was washing a little girl by the fireside. The following night L9 returned, accompanied by two other ships, and caused some damage in Suffolk. The next four raids were on a similar scale. Bury St. Edmunds was bombed in moonlight from a height of some 3,000 ft., the airship trusting to patches of fog to escape. Southend, always a favourite "fortress" for attack, suffered twice, three people being killed.

On May 17 Capt. Linnarz, very active about this time in command of one of the military airships, while over Ramsgate descried the lights of London, more than 50 miles away, for the first time; but his orders forbade him to go inland, and this most tempting of targets had to be left for another occasion.

The opportunity soon came. On the night of May 31 1915 Linnarz succeeded in bringing his ship over the metropolis, in reply, so the Germans alleged, for a bombardment of Ludwigshafen. This raid was carried out in full moonlight, a fact that shows how much there was to learn at the time in the art of air defence. The great size of the thickly populated area of London makes it an ideal target for promiscuous bombing. There was on this night only one raider, armed with an inefficient type of bomb, but 41 people were killed or injured, and £18,000 worth of damage was caused. The bombs all hit the eastern part of London north of the river; one of them fell into a tank at John Walker's whisky distillery in Whitechapel. Fortunately the tank contained water only.

Further raids in Yorkshire and Kent on June 4 had little result, but two nights later Mathy again attacked the north, this time doing much more harm than before. He found Hull, came down low over it, and killed 24 people, besides wrecking some 40 houses. The people of Hull, exasperated by this experience, broke out and smashed up a number of shops supposed to be German, but a better revenge was in store, for another one, Z27, that arrived to raid on the same night was totally destroyed by Lt. Warnford while it was returning home near Ghen, and fell in flames, one member only of the crew escaping alive. The first serious military damage in England was done by a single ship that raided the north on June 15. Some works in Yarrow were hit, 18 men killed and a number injured.

In commenting on the first raid on London on May 31, the Press had to come to the conclusion that it was in the nature of a trial trip, and this view was justified by the series of nine organized raids that took place in the latter part of 1915. The series of raids inauspiciously for the Germans, a Zeppelin engaged in bombing Dover being hit by a new 3-in. gun that had just been mounted there. She struggled across the Channel, losing gas rapidly, and fell into the sea near Ostend, where she was finished off by bombing aeroplanes.

London was reached on four nights during this period. Twice the results attained serious proportions. On Sept. 8 Mathy, now in command of L13, an improved type of Zeppelin, came and over the Wash, steered straight on London and bombed the City deliberately and with considerable success. Fires broke out in many places, and the damage done amounted to more than £5,000,000. Mathy also took part in the raid of Oct. 12, when his ship bombed Woodwich. On this occasion the casualties were 71 killed and 128 wounded. These losses were severe enough, but they were nothing to what the German public was led to the
believe; it was during this time that many of the airship commanders began lying freely, and "bombing" places they never went near.

The anti-aircraft defences had not yet been able to take the measure of the attack, and the good shooting of the Dover gun, mentioned above, was the solitary success that can be claimed for the ground defences up to the end of 1915. A few aeroplanes had been allotted to home defence, but they were quite unsuited for their task on account of their poor climbing power and their ineffective armament. The pilots, also, had but little training, and night landing grounds were few and very far between, so that ascents during 1915 for the attack of airships led nearly in all cases to fatal or serious injury to British pilots, and the attempt was looked on as a forlorn hope.

1916. The defences could now be tested in the early raids of 1916. Nine Zeppelins were reconnoitred over the Midlands on the last night of January, one getting nearly to Shrewsbury. Seventy people were killed. Out of 16 British aeroplanes that went up in pursuit, 8 crashed on landing. A month later 2 airships were able to sit over Hull and bomb it from a low height, without any interference from the defence. From this time, however, defence took an upward turn; the change for the better began to show about the beginning of April 1916 during the very next series of raids. L15, one of the five ships that attacked on March 31 1916, in attempting to reach Woolwich, was hit by the gun at Purfleet; it was then attacked in the air by Lt. Brandon, eventually falling into the sea off the coast of Essex. Mathy's ship was hit by a shell on the same night, but he managed to struggle home.

A wholesome dread of defended areas now began to be observable in the German tactics. For instance, during the last raid of this April series, Hull was undoubtcdly saved from further bombing by some new guns just installed there.

Fifteen airship flights were made over England and Scotland during this April period. Edinburgh was bombed with little effect; nothing came over London, although some bombs were dropped as near as Waltham Abbey. British losses were 84 killed during the series.

Further raids at the end of April were organized in conjunction with the naval bombardment of Lowestoft and Yarmouth, the whole operation being timed to coincide with the rebellion in Ireland. A large number of airships took part, but the result was small. London was saved from bombing by its defences on April 25. One Zeppelin ran out of petrol and was eventually destroyed on the coast of Norway.

The shortness of the summer nights prevented further raids until the end of July, when four attacks were delivered, indicating an ever-increasing respect for the defences. Twenty flights over England produced infinitesimal results, if we except the loss of Hull, of 10 lives. An abortive raid on Harwich was followed on Aug. 24 by an attack on London by Mathy, now in command of L31, a new Super-Zeppelin; he showed his usual dash, skilfully avoiding the defences by making use of clouds. He threw several 240-lb. bombs, the largest then known; they caused a few casualties and considerable damage in southeast London and round about Blackheath. The raid of Sept. 2 was carried out by 14 ships and was a determined attempt on London. The metropolis was undoubtedly saved by the brilliant action of Lt. Robinson of the R.F.C., who did not hesitate to attack the military airship Sl4, although she was under very heavy gunfire at the time. As he fired his third drum of ammunition into her, she burst into flames and fell, a burning mass, near Cuffley. The sight of this disaster was too much for the other commanders, who turned tail and made the best of their way home. British casualties included only three killed.

The next series of raids, begun on Sept. 23, 1916, was of great importance. The German command were not deterred by previous losses from again risking their best airships and pilots in the attack of London. They conceived, not unreasonably, that if London could be terrorized, they might touch the moral of the British Government, and so produce an appreciable effect on the conduct of the war. On Sept. 23 1916 the weather conditions over the North Sea were favourable for raiding. Eleven airships left German sheds, nine crossed the British coasts, and the main attack was directed on London by three of the newest Super-Zeppelins, coming in from the east and south-east.

Having crossed the Essex coast shortly before 11 p.m., L33 was over east London ten minutes after midnight. Here she dropped twenty bombs. London, however, was no longer the helpless mass of former days. The searchlights continually lit up the hull of the airship, which was at 12,000 ft.; she was badly holed by the guns, one of her engines was damaged, and she began to lose gas and fly clumsily. To add to her miseries, Brandon of the R.F.C. now brought his machine close up to her. For twenty minutes he stuck to her, pumping bullets into the fabric. As she laboured back towards the North Sea, the crew threw out everything they could lay their hands on, including the machine-guns. Her commander crossed the coast at Ormsby-in-Thanet, and decided to abandon his attempt. He thought she was going to fall into the sea was too much for him; he turned her about and came to earth three miles inland at Wigborough, near Colchester. A specimen of the latest type of Zeppelin thus fell nearly intact into British hands.

Mathy meanwhile brought his ship L31 in company with L33 up the English Channel and, turning in over the Kent coast, made straight for south London. On the way he dropped a few trial bombs to test his sighting. Approaching the defences, he handled his ship with great skill and succeeded in blinding some of the British searchlights, that were picking him up, by throwing out powerful illuminating flares. He passed straight over the centre of London, crossing the Thames near London Bridge. South London and the extreme north suffered severely; but, for some reason, Mathy threw no bombs in the central districts, where he could have done most damage. He got clear away this time, and went out to sea by Yarmouth. The handling of the companion ship, L32, was not of nearly so bold a character. Her commander began to hesitate as soon as he had crossed the coast of Kent, and he spent an hour circling about Romney Marshes. When eventually he started N. for London his courage again failed, and he kept edging off to the E. so as to avoid the central defences. His caution could not save him. As he crossed the Thames near Dartford he was picked up by lights and attacked by guns. In order to rise he dropped most of his bombs in open country. His efforts were of no avail. Brandon, who was still in the air, describes the ill-fated ship as being "hosed with a stream of fire." This was the attack delivered by Lt. Sovrey, also of the R.F.C., who succeeded in setting the ship on fire in several places; she fell in a mass of flames at Billericay, in Essex. The British casualties on this night were 47 killed, including one aeroplane pilot. The enemy would hardly see in this an adequate return for the loss of two new airships with their crews.

On the night of Sept. 25 four ships raidied the north, bombarding Sheffield, where 29 people were killed, and narrowly missed Manchester. Two other ships, whose commanders had already become noted for their caution, came up to the Norfolk coast but would not cross it. Mathy, on this occasion, took his ship on an entirely new line. Passing through the Straits of Dover, he flew up the Channel as far as the Isle of Wight, where he turned N. and went straight over Portsmouth. He dropped no bombs on the fortress or dockyard. Near Hastings he went to sea again on what was to be his last voyage to Germany.

Yet another serious attempt to bomb London was made on the night of Oct. 1. Eleven ships started from Germany. Three of them made an innocuous tour over Lincolnshire. Mathy in L31 came in over Lowestoft about 8 p.m. and as usual steered an excellent course on London. Soon after passing Chelsford, however, he found that the outer defences on that side of the capital were ready for him. A searchlight picked him up. He therefore turned and steered N.E. for some 15 minutes. Turning again he flew S.W., in order to get into position for his favourite dash down wind over the city. After drifting a few moments towards Ware, he set his engines going and started for north London at full speed. Suddenly a heavy gunfire was heard. The searchlights threw out all his bombs, at the same moment executing a very
remarkable right-hand turn that must nearly have broken the back of his ship. The pursuing aeroplanes were close upon him. He did all that was humanly possible to save his ship. He tried flying towards the W., on a zigzag course, rising and falling, in order to escape from the lights that continually held him, and from pilots who would not be shaken off. An airship once caught in such toils has little chance of escape. The end came quickly. Lt. Tempest came up to the ship at 12,700 ft. and brought her down in flames at Potter's Bar. Thus perished Mathy, the bravest and most skilful of all the German air destroyers. The fall of Mathy's ship had an immediate effect on three other raiders, who all made a sharp turn in for home the moment they saw it. After his victory, Tempest crashed on landing at North Weald Bassett, but was unhurt. During the whole of this great raid the only British loss was one man killed. The defence of London had now definitely got the better of the lighter-than-air attack; after this period no German airship ever flew intentionally over the metropolis. Deferred by the victory of the London defences, the German command turned their attention to the north for the final effort of 1916. They met with no better success. Of the ten ships that left Germany in the course of Nov. 27, eight came over land. One was destroyed on the coast near Hartlepool before midnight by Pyott of the R.F.C. She fell blazing into the sea. Although the pilot dived away at once to avoid the flaming mass, his face was scorched by the heat as she fell.

Another raider, L.21, after a remarkable journey right across England to Cheshire, was caught in the early morning just as it was growing light, when she was leaving the coast at Yarmouth. Three British naval aeroplanes came up with her. Cadbury attacked first, but exhausted all his ammunition; his experience was destined to be useful to him on a subsequent occasion. Another pilot then tried, but his gun was frozen up and jammed. The third pilot, Pulling, then went right in to within 60 ft. of the ship, under a heavy fire from her machine-guns, and succeeded in setting her alight. It is a curious fact that machine-gun fire was kept up from the gondola for a considerable time after the hull had begun to burn. She fell into the sea from 8,000 ft. and sank at once.

Other raiders, seeing the disaster near Hartlepool, turned for home again without attacking. Those who came in over land found that the ground defences were very different from what they had expected. The guns and lights were successful in keeping up a continuous fire on this occasion. The British losses were one man killed and three women killed.

During 1916 eighteen raids were made on England by aeroplanes and seaplanes. They were nearly all of the "tip and run" variety, and consisted in coming over the coastline, dropping a few bombs haphazard and getting away as soon as possible. The attacks were delivered with no apparent military purpose, and they had practically no effect.

The first aeroplane attack on London was made on Nov. 28, 1916 by a single machine; the weather was misty and the first intimation was the fall of six small bombs between Bromptoe Road and Victoria station. The raiding machine had an engine failure on the return journey and was forced to land within the Allied lines near Boulogne. Lt. Ilges, the pilot, had set out to take photographs and bomb the Admiralty.

Before the beginning of 1917 the defences had quite definitely beaten the attack, so far as concerned operations by ariplanes against London. Over the rest of England the airship commandants were tending more and more to avoid defended places, consequently the damage they could do was limited to objectives of secondary importance. It is a significant fact that of the nine Zeppelins put to flight by airship attacks in Jan. 1916 three had been killed and two others taken prisoner, their five ships being destroyed by the action of the defences, before the end of the year.

1917.—The three airship raids of the first half of 1917, carried out under the conditions indicated above, produced little result other than the loss of two of the raiders, one being shot down while on the way home by a French gun near Compiègne, the other being destroyed by one of the defending aeroplanes near Harwich. On the night of May 6–7 a single German aeroplane appeared over the East End of London, and dropped a few small bombs. The attack, in itself, was unimportant, but it afforded an indication of what might come later.

Before the end of 1916 it had become evident to the German command that, if effective bombing was to be kept up on targets that were worth attacking, it would be necessary to try new methods. Early in 1917, therefore, they began equipping a squadron with special machines suitable for bombing England systematically. This formation, known as the 3rd Bombing Squadron, was distributed in aerodromes about Ghent, roughly 170 m. from London. The new machines, of the Gotha type, were capable of flying with a full load of bombs at 12,000 ft. and over. They carried a crew of three, pilot and two machine gunners. In May 1917 the squadron was ready for action, and as soon as the weather became favourable the attacks were to begin. The raids, with the exception of two minor attacks on Harwich, were aimed at London, but on the first two occasions unsuitable weather caused a failure, and the bombs were unloaded in other places.

The first attempt on London came on May 25, 1917. The 3rd Bombing Squadron, 16 machines strong, left Belgium early in the afternoon and made the Essex coast about 5 p.m. On the Continent the sky was generally clear but there were thick banks of cloud over Essex. The task of navigating to London was found too difficult and the leader had to give up the attempt. He therefore turned S. over Essex and crossed the Thames about Gravesend, afterwards making a course S.E. Bombs were dropped on the Canadian camp at Shoorncliffe, where there were 100 casualties. The worst effect was produced in Folkestone itself. One bomb fell in a crowded street and killed 33 people, mostly women who were out shopping. Over England the opposition to the raid was entirely without effect, but one raider was brought down in the sea by a British machine working from Dunkirk.

The second unsuccessful attempt was made on June 5; 18 machines, practically the full strength of the 3rd Squadron at that time, left the Ghent aerodromes about 2 p.m. They made the Essex coast as on the previous occasion, but this time they turned S. earlier. They bombed Sheerness with some effect, the town and dockyard both being hit several times. The guns at Sheerness succeeded in hitting one of the raiders, which fell into the river off Barton's Point. A large number of machines were sent after it in pursuit. They were nearly all too slow and climbed too badly to do any good.

The third attempt on London was more successful. The whole of the 3rd Squadron started in the morning of June 13, taking the same course across the North Sea as before. A few machines were detached to bomb Margate and Shoeburyness. Probably this was done to confuse the defence arrangements. The main formation of 14 machines held on N. of the river to London, which was reached a little before noon. A few bombs were dropped in the East End and near the Royal Albert Docks; then, at a signal from the leader, the formation loosed 72 bombs over a small area having Liverpool Street station as its centre. The station itself was hit by three bombs. The casualties were severe—150 killed and 424 injured. One 100-lb. bomb hit a school in Poplar. On striking the building the bomb was torn in half before the fuse was lit, and only half the charge exploded; even so, 17 of the children were killed. A few isolated attacks were made on the raiders without success. One machine got into touch with the enemy over Ilford, but the observer, Capt. Keevil, was killed and the pilot's gun jammed. Such gunfire as was brought to bear in the London area was badly directed and had no effect.

The next raid on London on July 7 was also successful. Twenty-four machines started; they were first seen well out to sea soon after in the morning, flying at about 10,000 feet. Coming up to the coast, two machines were detached, as on the previous occasion, in order to attack Margate, where a couple of houses were wrecked. The main body of 22 machines, flying in diamond formation, crossed the Essex coast near the mouth of the Crouch river about 9.45 a.m., and they came on towards London,
AIR RAIDS

gradually climbing, until they were about 13,000 ft. over Brad- wood. The course of the raid ran by Enfield, where the formation turned S., over Edmonton and Tottenham. On the way to the City, St. Pancras and Shoreditch were bombed. The City itself received 26 bombs, one of them starting a small fire in the General Post Office.

The German formation was well handled in the way of making it a difficult target for the anti-aircraft guns. The machines flew in two divisions, with G's apart as they came under fire. The majority of the shell fired into the brown of the enemy burst harmlessly in the interval thus left. Individual machines flew with a switchback movement, alternately diving and climbing in order to make it difficult to find the direction at the guns more difficult. The anti-aircraft guns fired a very large number of rounds, but produced no effect at all on the enemy. The aeroplane defences again showed a lamentable lack of plan. Eighty-seven machines went up, of all sorts and sizes. A few were efficient fighting machines. Many of them, for all the good they could do, need never have left the ground. No scheme existed by which a combined attack could be delivered. In consequence, the enemy was quite well able to take off such isolated, though gallant, attacks as were made. They brought down two machines. All that the British pilots were able to accomplish was to finish off one lame duck, a machine that was in difficulties from the start. It fell into the sea off the coast of Essex and the crew were drowned.

The failure of the defensive arrangements, or rather the complete lack of efficient arrangements, began to cause considerable agitation in the public mind. The Germans were touching the nerve centre, and the British Government found it necessary to order a complete reorganization. The London Air Defences were to be formed as a separate command. It was to include all the means of defence, both from the ground and in the air. General Ashmore was brought from France to take charge.

On the formation of this new command several distinct problems presented themselves. Night raids on London by airships, though not very likely, were still possible; it was obvious that night raiding by aeroplanes would have to be faced. But the most threatening danger lay, for the moment, in day raiding by aeroplanes in force. To meet this, a line of guns was established to the E. of London some 20 m. out; and inside this line strong patrols of aeroplanes, working in formation, were organized. Careful plans were laid to ensure that the guns and aeroplanes would really cooperate and not interfere with each other.

A system of signals and directing arrows on the ground was installed to assist the pilots in finding the enemy. Outer patrols of aeroplanes near the coast could deal with the homeward journey of the raiders.

The new arrangements were soon tested; on Aug. 12 a party of nine Gothis made the land near Harwich. After following the coast to the Blackwater, they turned inland for London. The communication system of the defence control worked well, and the squadrons immediately defending London were at the required height in plenty of time to meet the enemy formation. The German commander, however, would not face the defences of London itself, and turned his formation about before they reached the outer line of guns. A number of bombs were unloaded on Southend as the enemy made off, and 32 people were killed. The Germans were thus able to take off the point of a new raiding series of gun-jams robbed the British pilots of success, and the only bag was one Gotha that was flying badly and was brought down in the sea by a naval machine.

An attempt on Aug. 18 was frustrated by bad weather. Many of the German machines were blown over Holland, where some of the pilots, thinking they were over England, dropped bombs!

An abortive attack on the Midlands by eight airships on the night of Aug. 21 was followed by the last day attack on England on Aug. 22, when Capt. Kline, commander of the 3rd Squadron, reported that he had to handle 10 Gothis in the air, while an equal number of naval machines turned the Sheerness bombers from their objective, and the German formation, harassed by the British pilots, wheeled south by Ramsgate. Here the anti-aircraft guns, working with great accuracy, shot down two of the raiders. A third was shot down off Dover.

The increased efficiency of the defences, both in machines and guns, decided the Germans to abandon day attacks, and they turned their attention to raiding with aeroplanes by night. Practically no answer had been found at the time to this form of attack, which had been carried on for more than a year on the western front in France. Searchlight staffs, in their then state of training, found great difficulty in picking up or holding an aeroplane in their beams. Gunnery, which could only be aimed roughly in the direction of the enemy, was so inaccurate as to be negligible. It was not thought possible to fly during darkness fast scout machines of sufficient climb and performance. Furthermore, it must be remembered that a pilot in the air at night can only see another machine when he is close to it, and that the performance of his engine dearies him to other sounds. At the time there was no way in which the pilot could receive information from the ground. For these reasons it seemed difficult to find any means on which to base plans of defence against night aeroplane raiding.

The first group of night attacks came in the beginning of Sept., and of those reached London itself. The raid on Sept. 2 was a quick affair at Dover and of little importance. On the following night, Sept. 3-4, about 100 hostile aeroplanes were reported near the North Foreland, and warnings were sent out by the central control a few minutes later when it was clear that they were coming up the Thames. Unfortunately there was serious telephone delay in getting the warning out at Chat- ham, and before cover could be taken a bomb had fallen on a drill hall in which a large number of naval ratings were asleep. No fewer than 136 were killed and 88 wounded.

Although on this night the defence was ineffective, certain points emerged which gave hope for the future. Three stout-hearted pilots went up in Camels, fast scout machines, and found that it was by no means impossible to handle them at night. In fact, being small and light, they were even easier to deal with than heavier machines, which would run on longer on the ground. The idea also evolved of barrage fire, a curtain of bursting shell to be put up in the path of the raiders.

The last raid of this moon period, on Sept. 4, reached London. The attacking machines, between 20 and 30 in number, began to come up to the coast soon after 10 p.m. While isolated attacks were made on Dover and Margate the majority of the raiders made for London. The barrage fire, organized since the previous night, turned some of the pilots, but 10 raiders reached the metropolitan area, and bombs were dropped in widely separated localities. The City, Paddington, Stratford, Hornsey, Holloway and Regent's Park, and other offshoots were hit. One bomb marred Cleopatra's Needle. Considering the magnitude of the raid, the damage caused was small, and the total casualties for the night included only nine killed.

Favourable weather and good moon conditions at the end of Sept. and beginning of Oct., 1917 produced a sustained series of raids, opening on the night of Sept. 24th with an attack on London by aeroplanes, in conjunction with an airship raid on Hull and the north.

The first aeroplanes were reported approaching Kent as early as 7 p.m., and by 8:10 p.m. some 37 machines in seven groups had come over the coast of Kent, Essex and Suffolk. Hull was heavily attacked, the gas-works were hit and several houses were damaged. Nine at least of the pilots attempted to attack London itself, but considerable improvement had by this time been effected in putting up barrage fire, which was successful in turning back all but three of the attackers. Of these three, one dropped bombs about Deptford and Poplar, doing but little damage; the other two passed right over London from north to south. A bomb dropped in Southampton Row killed 15 people who had not taken proper cover; others fell near the Ritz Hotel and into the river opposite the Houses of Parliament. Although 27 English machines went up they failed to find any of the enemy; the gunfire brought down one of the Gothis, which fell in the river near Sheerness.

The attack on the north was carried out by 10 airships under Capt. Strasser. After concentrating off Flamborough Head six of them came over land. Although Hull was found, the raid had very little success. This was partly owing to the cloudy
To avoid gunfire and aeroplane attack while over England, the ships flew at an immense height, well over 16,000 ft. At this altitude the efficiency of the crew is much impaired by height sickness and the intense cold. Another and fatal condition was produced by the weather. Near the ground the air was misty and there was very little wind, but at the height of the airships a strong gale was blowing from the N., and in this the Zeppelins drifted blindly S., the navigators being prevented by the ground mists from correcting their course. One airship passed over London without recognizing it and dropped a few heavy bombs; one of 50 kgm. fell in Piccadilly outside Swan & Edgar’s shop and caused some casualties. Owing to the peculiar conditions of the night, sound carried very badly, and this ship crossed London unheard. Eight other airships, in the course of their southern drift, passed, without knowing it, within easy reach of the metropolis.

Realizing that, on account of the ground mists, searchlights would have no chance of lighting up a high Zeppelin, the defence ordered them to remain covered unless an airship could be heard. The London public were inclined to complain that the usual display of lights and barrage fire was lacking. The lights, had they been turned on, must have produced the worst results. They could not light up the enemy, but they would be sufficient to show the attackers where London was, and to enable them to correct their course for drift. As it was, London was saved from a combined attack and the raid ended in disaster to the attackers.

One airship only returned to Germany in the usual way; six got back after flying over Holland or across the Allied lines. The remaining four were destroyed during the following day on French territory.

Aeroplane raiding was resumed during the moon period at the end of October. An attempt on the 29th failed on account of bad weather; another on the 31st was carried out by 24 machines. Considering that a good many of them got over London, the effect was small—one woman killed and damage to the extent of about £23,000.

The weather in Dec. 1917 was generally unfavourable for long-distance raiding, and only three attempts were made on London. The defences showed steady improvement. Two Gothen at last were brought down by anti-aircraft gunfire during a raid in the early morning of Dec. 6 on which occasion the Germans lost a third machine in the sea on the way home. On the night of the 18th, improvements in the searchlight control and the special training of the night-flying pilots began to make themselves felt. Twenty-seven defending machines of the best performance went up, and three combats took place.

As a result, one of the Gothen was so damaged that it fell into the sea off Folkestone and was destroyed. On this night the new "Giant" aeroplane came over London for the first time. It dropped one 300-kgm. bomb in Lyall Street, near Eaton Square, making a large crater but doing little serious damage. The whole raid, however, cost London more than £500,000 in damage.

On Dec. 22 the last raid of the year was frustrated by unfavourable weather; one Gotha was forced by engine trouble to descend near Margate, where it was destroyed by the crew.

1918.—In the five aeroplane raids of the first quarter of 1918 there was a tendency to replace the smaller Gothen machines by the new "Giants." A Gotha was destroyed by a defending aeroplane on Jan. 28. During this raid a bomb dropped by a Giant fell on a building in Long Acre that was being used as an airship hangar. The damage was considerable, but there were no casualties.

On the following night, Jan. 29, one of the Giant machines was pursued half round London by four of the defending scouts. The reason for its escape is curious. The British pilots saw over their sights a machine they imagined to be of Gotha size. The actual machine, being a Giant and very much larger, was therefore a good deal farther off than they thought, and they were firing at too long a range to be effective. The crew of the Giant became panic-stricken and were within an ace of landing when the British machines drew off.

Three Giants, unaccompanied by any smaller machines, attacked on Feb. 16; the only one that penetrated to Lon-
AIRSHIP—ALABAMA

Don demolished a house in Chelsea Hospital with a 300-kgm. bomb.

The raid of March 7, 1918 was remarkable as being the only occasion on which aeroplanes attacked London in the absence of any moonlight. The navigators of the attacking Giants were helped by a bright aurora. This made the night unusually light, and gave a constant bearing of fair accuracy to the pole. Warrington Crescent was badly hit, most of the houses being wrecked.

To turn to the airships, the disaster of Oct. 19–20, 1917 was followed by the destruction of four more ships by explosion in their sheds, and raiding was not resumed until the nights of March 12 and 13, 1918. Both these raids were made at an immense height, and although Hull and West Hartlepool were bombed, the damage did not amount to much. The casualties comprised nine killed on the two nights.

Five airships of the newest and largest type, under Capt. Strasser, attacked the Midlands on the night of April 12. Although more than seven tons of bombs were dropped in the neighbourhood of big towns, the result was very small, and only five people were killed.

The end of the airship raiding came on Aug. 5–6, 1918. Five ships came up to the coast of Norfolk, no bombs were dropped on land, but L7o, the latest word in airship construction, was destroyed, with Capt. Strasser on board, by Major Cadbury, flying a DH4 machine.

In the great aeroplane raid of May 19, 1918 the Germans made their maximum effort in this form of attack; between 30 and 40 Gothis of the 3rd Bombing Squadron took part, with at least two Giant machines. Thirteen of the raiders managed to get over London. The casualties included 49 killed, and £130,000 worth of damage was done in the London area alone. But the defence had by now made very real progress. Eighty-four aeroplanes, nearly all of excellent performance, went up in pursuit, and all landed safely. The anti-aircraft guns fired upwards of 30,000 rounds. The plans worked well in that the defending pilots were assisted instead of being hampered by the gunfire and searchlights. The Germans lost seven machines—three shot down in air combat, three destroyed by gunfire, and one from engine failure.

This success of the defence was final, and London was saved from further bombing. The Germans turned their attention to Paris, which now sustained a long series of raids.

A new system of defence control was in course of being installed in London at this time, but it did not come into full operation until Aug., and it was therefore never tested in an actual raid. It provided a method by which the defence commander could follow the course of raiding machines, and could instantly transmit information and orders to the pilots in the air by wireless telephone. It was calculated that this system would increase the power of the defence at least fourfold.

A proof of the efficiency of defence by aeroplanes, assisted by a good organization on the ground, was furnished by a squadron, manned by pilots trained in the London method, that was sent to France in June 1918 to cope with night bombing near the line. In a very short time they accounted for 26 German machines, and they practically stopped bombing in their area, with no loss to themselves.

Conclusion.—We have now traced the way in which raiding and defence grew up together, and the eventual success of adequately equipped and organized defences. In addition to casualties to aircraft and地面 troops, the German raids on England produced actual results by no means negligible. A night raid stopped munition work over a large area.

In order to establish a defence, men and material were kept back from France. This was particularly felt in the case of aeroplanes and pilots. Two hundred aeroplanes of the best performance and 200 highly trained pilots were available about London at a time when they would have been of the utmost value on the western front. The moral effect of raiding is found to depend not so much on actual damage as on the success or ill-success of defensive measures. In London, the barrage, the "aprons," and the aeroplane defence did much to allay fears that had arisen when there was apparently no answer to the attacks.

AIRSHIP: see AERONAUTICS.

AIKTEEN, JOHN (1839–1910), British physicist, was born at Falkirk Sept. 18, 1839. He was educated at Falkirk grammar school and Glasgow University, and trained as marine engineer at R. Napier & Sons, Glasgow. He lived at Falkirk, where he carried out his great experiments on atmospheric dust in relation to the formation of clouds and mists (1882), on the formation of dew (1885, see 8.136) and on the laws of cyclones (1891). His instrument for counting the dust particles in the air (see 8.714, 18.279) has been utilized in principle by many later workers. He also invented new forms of thermometer screens and powerfully aided the development of meteorology. He was elected F.R.S. in 1889 and was awarded the Royal medal in 1917. He also received the Keith medal (1886) and Gunning prize (1897) from the Royal Society of Edinburgh, in whose Transactions and Proceedings most of his valuable contributions were published. He died at Falkirk Nov. 14, 1910.

AKHWAN MOVEMENT, a religious revival or reform, confined mostly to the Nejd districts of Arabia. The term akhwon, or ʾikhwon, signifies "brethren," and the tenets of the brotherhood are those of Wahhabism revived and intensified (see 28.245). The movement, recognized by Ibn Saʿūd, Emir of Nejd, had taken definite shape after 1910; and in 1921 it still seemed likely to have far-reaching effects upon the attitude of the people of Central Arabia towards other Arabian communities and even to the outer world.

ALABAMA (see 1.459).—In 1920 the pop. was 2,248,774 as against 2,138,003, in 1910, an increase of 210,681, or 9.8%, as compared with 390,396, or 16.3%, in the preceding decade. Although the proportion of urban pop. was greater than in 1910, yet in spite of the marked development of mining and manufacturing interests, more than three-fourths of the inhabitants were still rural and chiefly agricultural. The urban pop. (inhabitants of cities of 2,500 or more) was 599,317; the rural, 1,638,857. The growth of pop. in the chief cities is shown in the following table:

The distribution of pop. by race was as follows: whites, 1,447,032; negroes, 900,652; Indians, 425; Chinese, 56; Japanese, 18; all others, 8. During the decade 1910–20 the white pop. increased 17.8%, while the negro pop. decreased 8.8% due to male negro migration to northern industrial centres.

Agriculture.—There were 256,990 farms in 1920; 262,901 in 1910, a decrease due to the negro migration noted above, but there was a marked increase in total production. The state Department of Agriculture estimated that in 1920 there were harvested 5,630,000 tons of commodities compared with 5,203,000 tons for the year 1910. The same Department made the following estimates of the acreage, production and value of crops in 1920—

Total harvested 11,117,900 $235,520,000
The above estimates did not include the acreage grazed or “hogged” and not harvested, which the state department of Agriculture placed in 1920 at 1,344,000 ac. with an approximate value of $80,001,000. The Statistical Bureau of the U.S. Department of Agriculture estimated the value of all crops in Alabama in the year 1920 at $249,000,000.

Mineral Productions—Three new lines of material progress during 1910–20 were notable: (1) The use of hydroelectric power; (2) shipbuilding; and (3) the utilization of the canalized Warrior and Tombigby rivers from the heart of the inland mineral district to tidewater at Mobile. A private corporation completed a great dam across the Coosa river and was in 1920 delivering electricity for lighting and power purposes to the chief centres of population and industry in northern and central Alabama; and the same company in 1921 began another great dam across the same river which would increase greatly the power available. In the meantime the U.S. Government, under the famous “Wilson dam” across the Tennessee river at Muscle Shoals. The impetus given to shipbuilding at Mobile continued after the World War; and the great shipyard at Chickasaw, a suburb of Mobile, was in 1920 steadily sending down the ways ships of heavy tonnage, made from steel fabricated in the Birmingham district and barged down the Warrior and Tombigby rivers. The growth of down-stream tonnage of coal, iron and timber on the canalized Warrior river continued for a year or two under private enterprise; but the closing months of the year 1920 marked a new era when the first vessel of a fleet of Government-owned and operated self-propelling barges made its way down the Mississippi river to New Orleans and into the Gulf, then to Mobile and up the rivers to Birmingham and Cordova in the heart of the Warrior coal-fields. A balanced tonnage, up and down stream, was steadily being developed in 1921 by the transhipment at Mobile of manganese ore from Brazil, for use in making high-grade steel in the Birmingham district, and by the establishment of an all-water freight rate from New York and other eastern points, via Mobile, to the various river ports.

Mineral Productions.—The Geological Survey of Alabama reported a decrease in 1918, as compared with the preceding year, in quantity but an increase in value of most of the mineral products of the state. In 1918 the production of coal was 1,011,692 short tons valued at $4,754,329, with a coke production of 4,893,599 short tons valued at $12,142,372. The iron ore mined in 1918 amounted to 6,121,675 tons at an estimated value of $15,334,501; the gross output of pig-iron marketed amounted to 2,645,179, valued at $80,863,678. Another important mineral product was graphite, of the value of which for 1918 was $125,000 compared with $71,951 in 1917. It was estimated that Alabama furnished over 60% of the domestic graphite used in the World War. The impetus given to public education, under the administration of Governor Wilson Kilby, the system of county high schools and by more liberal appropriations both for the common schools and for the institutions of higher education, lost none of its momentum under his successors. In the beginning of Governor Kilby’s administration the Legislature passed an Act, approved Feb. 6, 1919, creating a commission of five members, appointed by the governor, to make a study of the educational system of the state with the object of determining its efficiency. The commission in turn invited the U.S. Bureau of Education to accept the task. The result was a series of Acts passed in 1920 regulating the system of education in the state of Alabama. Among the most important of these Acts was one providing for a state Council of Education to coordinate the efforts of the university at Tuscaloosa, the Alabama Polytechnic Institute at Auburn, the Alabama School for Girls at Montevallo, the Alabama Agricultural and Mechanical Institute and College for women at Montevallo, by assigning to each special fields for higher education. The efficiency of the public-school system of the state was perhaps best shown by the steady reduction in the number of total public school children during the two years preceding 1919, from 278,082, of which number 210,690 were negroes, 65,394 native whites, and 1,893 foreign-born whites. During the two-year period before the World War, the percentage of illiterates in the total population, white and negro, between the ages of 10 and 21 years, increased 5.2 per cent.

Taxation and Finance.—Owing to the limitation in the constitution of the state as to the valuation of real and personal property to 0-65% upon assessed values, the Legislature in 1919, in an effort to increase revenues, incorporated in the general revenue bill among the license or privilege taxes a tax of two cents per ton on coal and three cents per ton on iron mined in the state, payable monthly. At the same session a graduated income tax, ranging from 2% to 4% was levied; but the Supreme Court decided that it was inconsistent with the constitution and nullified the law. The amendment to the constitution as hereinafter noted, authorizing the issue of $25,000,000 in bonds, was adopted by a joint vote of the state and the voters. The Constitution of 1901 was submitted for adoption according to the strict terms of the constitution by an extra called session of the Legislature.

History.—During the period from 1910 to 1921 the Government of the state remained in the control of the Democratic party with little more than nominal opposition by the Republican party, the educational, property and other qualifications for voters under the Reconstruction Act of 1867 being eliminated by a new constitutional amendment passed by a large majority of the Republican voters. It was only in the presidential election of 1920 that there were indications of the development of a real white Republican party in the state. In that election that party polled practically one-third of the vote cast, 31.9% thus securing the privilege of a primary for the nomination of candidates in the next election at the expense of the state Government. Before this time factional differences in the Democratic party were fought out in the primary election for state superintendents, and the general elections were merely formal ratifications of the choice made in the primaries. It was not easy to distinguish clearly between the two leading factions, but the dominant influence was the “Conservative” and “Progressive” suffrage, and the two factions determined the line of cleavage. The former insisted on the fullest protection to vested financial interests, and before the adoption of the Eighteenth (prohibition) Amendment in 1920 a railroad company in Alabama, publishing a liberal policy of “local option” in the manufacture and sale of alcoholic beverages. The latter stood generally for strict control, by the state, of corporate capital, especially in the matter of railway rates and regulation, and for prohibition of the liquor traffic. Several amendments to the state constitution of 1901 were adopted during this period, most of them dealing with matters of local interest to counties and cities. Two, however, were general in their scope and on the November ballots of 1919 and 1920 the voters approved the amendment of 1919, which provided for local taxation by counties and school districts as to increased taxation in the interest of public schools; the other authorizing the issue of state bonds to the amount of $25,000,000 for the purchase of a certain amount of buildings to enable the state to secure the national appropriations in aid of that policy. At its regular session in 1919 the state Legislature refused to ratify the Nineteenth Amendment to the Constitution of the United States providing for woman suffrage, as the number of states had made it a part of the Constitution, Governor Kilby called a special session of the Legislature (1920), which promptly passed an Act providing for the registration of women voters and for other election measures, but refused to effect the provisions of the Amendment. The total number of men enlisted for the World War in the state and indrafted into the army was 75,811. As this did not include the number of men who joined the U.S. armed forces by other routes, the Department of Labor estimated that approximately 160,000 men served in the Army. Alabama, a total number of $199,838,400 to the Liberty and Victory loans.

Governors: Leonidas Sexton, 1833–67; Robert G. Conner (Dem.), 1907–11; Emmet O’Neal (Dem.), 1911–5; Charles Henderson (Dem.), 1915–9; Thomas E. Kilby (Dem.), 1919–.

ÅLAND ISLANDS (see 1,469).—The alarm that had been felt in Sweden for some years at Russia’s projected military works in the Åland Is. was intensified in 1915 when Russia openly began the construction of fortifications. Swedish protests against this breach of the Convention of Paris (1856), and Russia’s assurance that the fortifications were merely temporary did not allay Swedish hostility towards Russia which at times threatened a crisis. The Russian revolution of 1917 diverted attention from the fortifications to the larger question of the sovereignty of the islands. In Aug. 1917 the Åland islanders took steps to consider reunion with Sweden, and a plebiscite in December showed 95% of the population in favour of the proposal, a petition to that effect was presented to the King of Sweden in Feb. 1918. The King in reply echoed the hope of the delegation that a solution of their desires might be found “in concert with free and independent Finland.” In the same month Sweden sent a military expedition to the islands to protect the population from outrages by the Russian Bolshevik garrison with which a small Finnish White force was unable to cope. The Russians were sent to Åbo and the Finnish troops to northward of Åland, and in Sept. 1918, the German garrison by invitation of the Finnish Whites, the Swedish force withdrew. The German garrison remained until Oct.
ALASKA

1918. The Treaty of Brest-Litovsk (March 3, 1918) and the subsequent treaty between Germany and Finland (March 7, 1918) both stipulated that the fortifications on the islands should be removed and not subsequently rebuilt. But the work of demolition was repeatedly delayed. The Finnish Government opposed the Ålanders’ wish for union with Sweden, but proposed to compromise by making the islands into a separate Finnish province. The Diet persisted in this policy, and passed a bill for self-government for Åland in May 1920. Meanwhile the appointment of a Finnish military governor caused resentment, which was aggravated (July 1918) by attempts to call the Ålanders for military service on the mainland. They refused to obey, and at the same time expressing their willingness to serve in the islands under Swedish-speaking officers. Many of the inhabitants fled to Sweden in order to escape service. In Nov. 1918 the Ålanders appealed to the United States, Great Britain, France and Italy, relying on the right of self-determination. An appeal to Finland at the same time drew an equivocal reply. In Feb. 1919 the Ålanders submitted their case to the Supreme Council in Paris. Sweden supported their claim. The Peace Conference declined to deal with the matter, which was then referred to the League of Nations. A commission of three jurists appointed by the League reported (Sept. 1920) that the Council of the League was competent to make recommendations since the dispute did not refer to a matter left by international law to the domestic jurisdiction of Finland. The League thereupon appointed a commission to examine the question.

Opinion in Finland among both Finns and Swedes was strongly opposed to the cession of the islands, and it was argued that to yield to the demand for self-determination of a fraction of the Swedish population of Finland (about one-tenth) would be to reduce the doctrine to an absurdity. At the same time the opposition of the Swedes in Finland to the Ålanders’ desire might be inferred as biased by unwillingness to lose the weight of their vote and so lessen Swedish influence in Finland. Finland also maintained that her sovereign rights over Åland were not affected by Russian domination in Finland or by subsequent events, and that Finland was not one of the “new” states that arose as a result of the World War; and that in consequence the Åland question was purely a domestic one in which no other state nor the League of Nations was competent to intervene. On the other hand the Ålanders showed themselves virtually unanimous in their desire for union with Sweden, to which they were closely allied in race, language, and to a great extent in trade, and they maintained that their islands were sufficiently distinct, both physically and geographically to give them the right of self-determination.

The commission, after visiting Stockholm, Helsingfors, and the Åland Is., presented its report to the Council of the League at its session in June 1921. On June 24 the Council announced its decision that the islands were to belong to Finland, but that they were to be neutralized from a military point of view and given full guarantees of unfettered autonomy. M. Branting, on behalf of Sweden, said Sweden would bow to the League’s ruling under protest, and M. Hyman was appointed to preside at a committee of Finns and Swedes to discuss details of the guarantees.

For a general account of the islands reference may be made to Handbooks prepared under the direction of the Historical Section of the Foreign Office, No. 45, Åland Islands; also Atlas de Finlande, with text in French (1910). The Finnish side of the present dispute is set forth in The Åland Question and the Rights of Finland (1920); see also Sven Tumbo, Les îles d’Åland dans l’Histoire (1919), and E. Sjöström, La Question des îles d’Åland (1919). (R. N. R. B.)

ALASKA (see 1,472).—The most important events in the history of Alaska in the ten years ending with 1920 were: (1) the extension of surveys and investigations of resources over nearly half of the total area (356,400 sq. m.); (2) the change in the public land policy, which no longer prohibited the utilization of Alaska’s coal, petroleum and water powers; (3) the granting of a measure of home rule to the people of Alaska; (4) the improvement of transportation by the construction of a Government railway from an open port on the Pacific to navigable waters on the Yukon river, by the construction of many wagon roads (total roads and trails 4,000 m.) and by the installation of many lights and other aids to navigation (total 547); and (5) the great advance of her copper and salmon-fishing industries, and of gold mining until 1916.

Public Land Policy.—The political history of Alaska has largely centred in a struggle for more liberal land laws. In early days copper had been considered for the best interests of Alaska to transfer the lands to private ownership as quickly as possible without too close a scrutiny of the means employed. This policy was completely reversed as a result of the conservation movement inaugurated under President Roosevelt. The aim of the movement, as first defined, was to prevent waste of natural resources; but this issue proving too academic to make a popular appeal, it gradually veered to a protest against corporate control of lands and resources. Though supported in the beginning by the best element in the nation, it ultimately became involved in the bitter struggle between the Roosevelt and Taft wings of the Republican party. As practically all the lands of the Territory were still owned by the Government, the withholding of the most valuable of these from settlement and development played havoc with her industries. Curiously enough, the most ardent of the conservationists failed to recognize the urgent importance of conserving the salmon and halibut fisheries. As it was, the withdrawal of coal, oil and good timber lands as well as of water powers left the Territory with only metallic deposits and fisheries on which to base its industries. A very important by-product of the conservation movement was the development at Washington of a mania for the establishment of reservations in Alaska. In this way there were set aside for various purposes, exclusive of mineral or forest withdrawals, some 46,000 sq. miles. For many years the Alaska conservation issue remained at a deadlock between the executive and legislative branches of the Government. Meanwhile Alaskan industries languished. With an abundant supply of fuel close at hand, she was forced to import coal and petroleum at great cost; her pulp wood was rotting in the forest, her water powers were undeveloped. Only gold- and copper-mining and salmon-fishing increased. Finally during the Wilson administration a leasing policy for coal and oil lands and water powers was established by law. At about the same time the shortage of paper had a liberalizing influence on the regulations relating to the sale of the lands of the federal government. In 1921 the new laws were too recent to allow an estimate of their effect.

Government.—The struggle of Alaska to attain representation in Washington, lasting nearly 40 years, resulted in 1906 in the authorization of an elected delegate to Congress. At each biennial election which followed, home rule was the only important issue, until finally in 1912 an Act was passed granting a territorial government. This continued the governor as a presidential appointee, and (unwisely, though in accord with American tradition) provided for a bi-cameral Legislature. The upper chamber, or Senate, consisted of two senators from each of the four judicial districts, serving four years. Sixteen representatives formed the lower chamber, or House of Representatives, four elected for two years from each judicial district. This equal representation for each of the judicial districts gave the less-populated areas of the interior an unjust preponderance in the Legislature, and in many instances worked against the best interests of the Territory as a whole. Congress in the organic Act expressly retained the right of repealing all laws enacted by the Alaska Legislature. Furthermore, the Territory was denied the right to enact laws relating to the excise, game, fish, fur, features along the entire coast-line and covered about 10% of it in detailed surveys of important harbours and principal routes of navigation. In 1913 the International Boundary Commission completed the survey of the Alaska-Canadian boundary.
bearing animals, or the existing Federal licence tax. It was provided that the capital should be at Juneau. The first session of the territorial Legislature was in March 1913, and the first law passed gave the franchise to women. Since that date the most important legislation has related to mining, hours of labour, workmen’s compensation, banking and education. Heavy taxes were also imposed on the salmon-fishing industry, and from these the Territory derived a large part of its income. In 1916 the Legislature approved an application on the part of the had transportation and manufacture of all alcoholic beverages. The vote was in the affirmative by 7,928 to 4,433. As the Legislature had no power to change the excise law, a petition was submitted to Congress, which passed a dry law for Alaska in 1917.

Education.—The white schools of Alaska were in 1920 under territorial management and were supported by local taxes. Even most of the small settlements had schools, and five of the larger towns supported high schools. The Territory founded an agricultural and mining college at Fairbanks in 1918, but as funds were appropriated only for the erection of a building, the school had not opened as of 1919. In 1919 there were 62 white schools in the Territory, with 1,477 teachers and 2,713 pupils. The education of Alaskan Indians and Eskimos was in the hands of Federal agencies. In 1910 there were in the Territory 70 Indian schools, too few to accommodate the children of the 25,000 natives. The Federal Government also made some provision for medical service for the natives, and maintained six small hospitals for the purpose. In addition to the Government schools, about 35 missionary schools were maintained by various churches for the benefit of the natives. Many of these had boarders-schools and a few hospitals.

Population.—In 1920 the pop. was 34,890, a decrease of 9,457, or 21.7% from 44,345 in 1910. The whites numbered 29,000, as against 36,400 in 1910; the Indians and Eskimos 25,000, as against 25,337 in 1910; and the balance was of Mongolian and other races. Juneau, the capital and an important mining centre, was the largest town, with a pop. of 3,058. Ketchikan, the most important fishing centre, had 2,458. Anchorage and Seward, on the Government railway, had respectively 1,685 and 632. Cordova, the coastal terminus of the Copper River railroad, had 955. Fairbanks, the chief mining town of the interior, had 1,155. Normal population of Alaska steadily increased until 1915, when it exceeded 40,000. Subsequent losses were due to: (1) enrolment in military service of about 3,500, men of whom returned; (2) high wages in the States; and (3) decrease in the gold-mining industry. While in 1915 about 9,600 men were employed in Alaska mines, there were only about 3,000 in 1920. In addition to the permanent residents of Alaska, between 25,000 and 30,000 men annually visit the Territory to find employment, chiefly in fishing, but also in mining. There were also 2,000 or 3,000 tourists each summer.

Mountaineering.—The mountain ranges include a number of the highest peaks on the continent, which have exercised a fascination for the mountaineer. Many unsuccessful attempts were made to reach the summit of Mt. St. Elias (18,024 ft.) before the Italian Duke of the Abruzzi finally succeeded in 1897. Mount Wrangell, Alaska’s highest peak, was ascended by a party of 10 in 1912, and in 1912 Donna Keen climbed Mt. Blackburn (16,110 ft.). Several attempts were made between 1903 and 1910 to climb Mt. McKinley, the highest peak in North America. William H. and Peter Anderson, prospectors, reached the summit of the N. peak (20,000 ft.) in 1910, and Hudson Stuck and Harry P. Karsten the summit of the S. peak (21,500 ft.) in 1910. Katmai volcano, in the central part of the Alaska Peninsula, has been smoking without interruption for more than a century previous to 1912. On June 6 of that year, without previous warning, the top of the volcano blew off and ejected matter for at least 1,500 m., while the fine volcanic dust, which followed, caused a change of climate in every part of the world. The eruption was one of the greatest eruptions in historic times, it caused no loss of life, because the ejecta fell chiefly on the sea and in uninhabited regions.

Railways.—At the close of 1910 there were 371 m. of railway in the Territory. All except a small entry in the Bering Sea (narrow-gauge) which ran inland from Skagway across the international boundary to White Horse in the Canadian Yukon (110 miles). This line, while primarily serving Canadian territory, gave access during the open season of navigation to the settlements on the lower Yukon, extending from Cordova on the coast to the Chitina copper belt (106 m.), was completed in 1910. Another line, the Alaska Northern Railway, with standard gauge, was built from Seward to Cordova. A third line, the Seward Peninsula and subsequently abandoned. In 1912 Congress authorized a special commission to report upon the Alaska railway situation. The commission recommended that 733 m. of railway be built, estimated at $5,000,000. The bill was passed by two lines: one to extend from Cordova to Fairbanks, using the Copper River railroad, with a branch to the Bering River coal-field; the other to run from the town of Fairbanks through the lower Susitna valley to navigable waters of the Kuskokwim river, with a branch into the Matanuska coal-field. In 1914 authorization for not more than 1,000 m. of railway construction, the cost limited to $254,000,000, was granted by Congress. This commission was then appointed, and after extensive surveys confirmed in general the former estimate of cost. In 1915 the administration announced the selection of a railway route from Seward to Fairbanks. The estimated cost of this was about $1,000,000,000. A route from the south was extended to the south of the Yukon and the method of navigation. It was decided to use as many as several million dollars.

Commerce.—The value of the total products of Alaska from the annexation in 1867 to the close of 1920 was more than $1,000,000,000. In 1919 Alaska produced minerals, furs, fish, etc., to the value of nearly $200,000,000. Of this the value of copper was $38,265,000, from which $1,449,000 was for merchandise from foreign countries. In 1919 25 American vessels (tonnage 32,444) and 5 Canadian vessels (tonnage 4,870) were operated as common carriers of Alaska ports; the tonnage of vessels was 9,105,815. Native vessels of 32,803 tons northbound, and 278,200 tons of freight and 37,717 passengers southbound. In the same year a total of 370 private vessels (514,000 tons) were carried on the Alaska service and carried a total of 456,500 tons of freight (both- and southbound). Nine river steamers were operated on the Yukon in the summer of 1919. These carried a total of 9,610 tons of cargo and 1,720 passengers. One steamer was operated on the Kuskokwim river in 1919.

Mining.—From its small beginning at Juneau in 1880 up to the close of 1920 Alaska mining yielded a total value of $800,000,000. Of this 96% is credited to the copper deposit. The mines have also produced silver, platinum, palladium, tin, lead, antimony, tungsten, chrome, coal, petroleum, mica, graphite, barite and sulphur; and development work was done on deposits of nickel, iron, and molybdenite. The value of the total annual mineral production rose from $16,890,000 in 1910 to $22,000,000 in 1920. Alaska mines have produced $320,000,000 in 1919, of which $220,000,000 was gold. The largest gold production of any one year (1906) was $22,000,000. Since 1916, when the value of the gold output was $17,000,000, gold-mining has steadily declined, being only $8,000,000 in 1920. The cause of this was world-wide depression, caused by the economic conditions brought on by the World War, and to this primarily is due the loss of population already referred to. In the past about 60% of Alaska’s population has directly or indirectly been dependent on mining. The U.S. Geological Survey estimated the value of the placer gold reserves of Alaska to be at least $500,000,000. This was in addition to the gold in vein deposits whose value could not be estimated. Auriferous lodes have been found in many parts of Alaska and developed in a small way. The only large gold lode mines were in southeastern Alaska. Before the war there were near Juneau a number of small large gold mines, the most valuable being those of the Tanana district. There are high-grade auriferous and some anthracite in both the Bering River and Matanuska districts, the latter within reach of the Government railway. All Alaska coal lands were withdrawn from public entry until 1910, and 125 were set aside for claims previously entered. This interdict lasted until 1915, when a coal-leasing law was enacted. Coal-mining was still in the development stage in 1921, the entire production up to that time being 375,000 tons. This coal was taken from a Government mine in the Matanuska field. The total
ALBANIA

reserves of coal in the surveyed fields of Alaska were estimated to be 12,000,000,000 tons, and these were found at four localities on the Pacific seaboard: namely, Yakataga, Katalla, Inskin Bay and Cold Bay, and also at several places near the N. Arctic coast. Only at Katalla, 60 m. E. of the mouth of the Kuskokwim River, any considerable drilling had been done, and some oil production from the only petroleum claim to which a patent had been granted. The withdrawal in 1911 of all lands from entry stopped all development. In 1919 an oil leasing law was passed, and the acreage of producing fields and expected oil output were increased. The total Alaska oil production to the close of 1920 was 60,000 barrels. Meanwhile, the Territory was consuming about 5,000,000 barrels of oil annually, and almost all its production was consumed by railroads, mining operations, and military installations. The value of the oil oil consisted of about 10,000,000 barrels, or 5,000,000 tons of lead. This had practically all been won from gold and copper ores, for no large deposits of silver and lead had been developed. The mining of platinum and related minerals began in 1916, since which time about 1,000 oz. of those minerals had been produced. Demand for the War led to the mining of some antimony, tungsten and chrome ores, but with the decreased value of these metals after the war, the mines have ceased operation. Quicksilver had been cast out in a small way for many years. There were in south-eastern Alaska extensive deposits of high-grade marble which had been quarried on a large scale.

The total value of fish products which had been marketed (1867-1919) was $124,800,000. In 1919 the output of the fisheries was $26,500,000, of which $2,500,000 was for salmon. Two small salmon canneries were built in Alaska in 1879, and before 1919 the total output was $174,000. The enormous catch of 1919 was due to the stimulus of the war demands, and was undoubtedly in excess of the number that can be taken without permanently impairing the industry. In the early days of the salmon-fishing the catch was distributed on the spot, but, beginning in 1910, steps were taken to regulate the fisheries. The large catch of 1910 (500,000,000) was a great improvement on those preceding it, but is by no means adequate. As an additional precautionary measure, hatcheries were established. There were 18 hatcheries in 1910, and in 1919 there were 21, which had produced 95,480,000 young salmon. In theory this should suffice to provide for the annual catch, but in practice only a small part survives to adult in the waters. The fisheries have been in a bad way for some time, as the Alaska salmon fisheries is indicated by the fact that in 1919 a total of 13,568,000 lb. of salmon were shipped from the Territory. The halibut fisheries are being depleted even more rapidly than the salmon, and in 1920, 1,100,000 lb. were caught, and of this, 300,000 were exported each year. The industry employs about 900 men and 90 small vessels. The halibut is all shipped fresh; much of it to the E. coast markets, and some to Europe. The number of cod on the Alaska coast is not great, but is still being increased. In 1919, 1,300,000 lb. of cod were landed. The total annual catch is between 10 and 15 million pounds, and the number of men employed is only a few hundred. Herring are found in great abundance as far north as Unalaska. Whales were numerous in Alaska, but, as a very important industry, is now limited to a few shore stations, where the catch is chiefly used for making fertilizer. There has been some canning of crabs and clams. The Alaska crab, which is the same species as that found in the Pacific waters farther south, is especially delicious.

Forest Products.—The national forests of Alaska include about 10 per cent of the total area, or 29,00,000 acres. These are estimated to have a timber value of $77,000,000 at 75% (H.M.) of timber suitable for lumber and pulp. Up to 1923 these forests had been used almost solely for local use, though some space had been exported for the manufacture of aeroplanes and other articles which require great strength of wood. Early in 1923 it was estimated that the forests were capable of furnishing 2,000,000 cords of pulp-wood annually. A pulp-wood industry was developed in south-eastern Alaska in 1920.

Two important railroads were completed in Alaska during the war. The Alaska Railroad, between Fairbanks and Seward, was built by the American Express Co., and was completed in 1915. There are plans for extending it through the Yukon valley to Dawson City, and also to the White River. In 1916 the Portage and Seward Carrying Railroad connected Seward with the coast, and was extended to the south-west in 1919.

Bertha, A., "Alaska: Past, Present and Future." A. B. H. (1911). ALBANIA (see 1487).—Up to 1908 the policy adopted by the Albanian people was to preserve the Ottoman Empire until such time as the Albanian nation’s national ideal, surreptitiously propagated by the various national societies resident abroad, had entered into the consciousness of the Albanian people as a whole (a process necessarily slow where 90% of the population were illiterate and of a face of such mixture of Islam’s Albanian-Hungarian and the Greek Patriarchate) lest a premature disruption of Turkey might bring about the dismemberment of Albania herself at the hands of her Christian neighbours; (2) in the meantime by constitutional means for an autonomous administration of Albania.

Prominent among those in favour of this Fabian tactics were Ferid Pasha Vlorë, the Sultan’s trusted grand vizier, and his cousin Ismail Kemal. The keen appreciation by these statesmen of their country’s predicament was amply proved by subsequent events. These events began in July 1919 when the Young Turk revolution became imminent. The Albanian mountain chiefs, throwing in their lot with the revolutionary movement, took the lead by telegraphing to the Sultan to demand the revival of the constitution of 1878. A few days later Maj. Enver Bey and the Committee of Union and Progress proclaimed the constitution at various places in Macedonia, and the II. and III. Army Corps threatened to march upon Constantinople. On July 24 the Sultan bowed to the inevitability. Six months later he was deposed after his attempt at counter-revolution had failed—an attempt undertaken with the aid of his Albanian bodyguard and with the
convenience of the Liberal union, headed by Ismael Kemal, who had already realized that the aims of the committee were little more liberal than the old régime's. The privilege of inform- ing him of this decision of Parliament was reserved for another Albanian, Essad Pasha.

The Albanians had at first hailed the Turkish revolution with enthusiasm. It seemed to promise the fulfilment of their most cherished aspirations: autonomy and the introduction of means of education in the national tongue. Albanians had never been slow to avail themselves of any opportunity of educating themselves on national lines, as is proved by the phenomenal progress in education that had been made within Albania itself during the years 1879-86, when the establish- ment of Albanian schools was tolerated, as well as in the Albanian colonies abroad. The names of men like the brothers Sami and Naim Frashe, the first a lexicographer and historian, the second a poet; of Wassa Pasha, founder of the society for the publication of Albanian books in Constantinople in 1879; and of Prenk Doci, who became Abbot of the Mirditi in 1888, should especially be remembered in connexion with the obscure but heroic efforts on the part of patriotic Albanians to educate their countrymen prior to the revolution of 1908.

A "Bessa" (pledge of honour) was taken by the mountain tribesmen to suspend all existing blood feuds in honour of the auspicious occasion. It soon became evident, however, that not only was nothing to be hoped for from the Young Turks but that the triumph of the revolutionary movement was to prove a more formidable menace to the cause of Albanian nationality than the obscurantist tyranny of the Sultan. The Committee of Union and Progress had no sooner obtained a settlement of the international questions arising out of the annexation of Bosnia-Herzegovina and of Eastern Rumelia by Austria-Hungary and Bulgaria respectively, than they actively set to work to achieve their plan of Ottomanizing the subject races of Turkey. The Albanian schools, which had recently been able to open their doors through private contributions, were again closed, the Albanian newspapers were again forced to migrate to foreign lands, and the national movement was stopped. In the face of violent protests a decree was issued that the Albanian lan- guage might be taught with the Turkish instead of Latin characters and a number of school-books were actually published in this manner. But the Albanians saw through the device and worked to nullify it. Hopes of the books were burned in the market-places.

Insurrection of 1911-2.—At the same time an insurrectionary movement broke out among the Moslem tribes in the north, headed by Isa Boletin, a natural leader of rare prowess who rallied the mountain tribesmen disaffected by the attempt of the Young Turks to levy taxation from which hitherto they had been exempt. The Turks, however, retaliated by ruthless efforts to disarm the population. Whole villages were destroyed and —what the proud clansmen would less easily forgive—their chiefs were publicly flogged. In 1911 the insurrection assumed larger dimensions. While the Moslem tribes kept quiet the Roman Catholic Malzia and Mathe tribes, instigated by the Montenegrins, formed armed bands, and in the spring attacked with success the Turkish outposts on the Montenegrin frontier. In April Torgut Shevkut Pasha tried to suppress the movement with a large army, but notwithstanding the superiority of his forces, met with several reverses. In May Russia warned the Ottoman Government not to extend hostilities against Montenegro, who was harbouring a large number of the refugees. In June Mirdita joined the rebels, proclaiming her own autonomy and declaring herself a national government. At this juncture, there was a great meeting of rebel chiefs, who drew up a state- ment of their grievances and a list of their demands under 12 headings, of which the most important were the recognition of Albanian nationality and the use of the Albanian language in the schools and in all local administration.

Balkan War, 1912-3.—The Turks attempted to bribe and cajole Mgr. Seregi, Archbishop of Scutari, a brave and honest patriot, to intervene. He protested that he had not the authority; nor was it his business. The inevitable result was that the follow- ing year, when the Turks were fully engaged in the war with Italy, the insurrection broke out afresh. The Albanians of Kossovo joined in the revolt, seized Pristina, and published a manifesto demanding a dissolution of Parliament and the holding of fresh and fairly conducted elections. Southern Albania joined the insurgents and success followed success. In May Uskub was occupied. In view of trouble brewing elsewhere the Turks had no alternative but to give in. By the terms of the cessation of hostilities, Albania was recognized by the Turkish Government as an autonomous administrative prov-ince comprising the four Albanian vilayets of Scutari, Kossovo, Yannina and Monastir, and more or less the same conditions already granted on paper were definitely ratified. Of all these concessions, however, by far the most important was the recognition on the part of Turkey that Albania extended to the four vilayets. This was the first official delimitation of the frontiers of Albania.

The success of the Albanians was, no doubt, a considerable factor contributing to the outbreak of hostilities between Turkey and the Balkan League in the autumn of 1912. The latter were encouraged by the reverses sustained by the Turkish army under their German leaders, and the grant of autonomy, were it allowed time to consolidate the national organization of the country, threatened to jeopardize the aims of the league, which envisaged the partition of Albania. The latter suffered from possessing no effective central authority. Accordingly, when the war broke out in Oct., the Albanians were divided as to the right policy to pursue. The Roman Catholic Maltsors joined the Montenegrins; the Kossovo Albanians fought half-hearted on the side of the Turks; the rest of the Albanians remained neutral. The Maltsors, moreover, withdrew from the struggle before the end of the hostilities, being enraged at the cruel treatment by the Montenegrins of their Moslem neighbours. In fact, apart from the defence of the two fortresses of Yannina and Scutari, the safety of which was considered a vital point to the life of Albania, the Albanians practically left the Turks alone in their struggles.

During Nov. the greater part of northern and central Albania was invaded by the Serbians and Montenegrins, and the greater part of Epirus was in the possession of the Greeks. Albania seemed lost. But at this juncture the prompt action of Ismael Kemal not only saved Albania, but enabled the Governments of Austria-Hungary and Italy, the two Powers interested in the maintenance of an integral Albania, he landed in the nick of time at Durazzo before the capture of that town by the Serbians. Thence he proceeded on horseback to Valona and summoned there an assembly of representative notables from all parts of Albania. On Nov. 28 1912 the national flag, the black double-headed eagle of Scanderbeg on a blood-red ground, was hoisted over the town and a formal proclamation of independence was issued together with a declaration of neutrality. This act gave the Austro-Hungarian and Italian Governments the necessary lead for their diplomatic inter-vention. But owing to the championship of Russia of the allies' cause, the only immediate result of this was the menace of a general European conflict. It was left to England, the only Power with any pretensions to impartiality, to lend her best offices to bring about an accommodation, and it was owing to the untiring efforts of Sir Edward (afterwards Lord) Grey that eventually a peaceful but by no means altogether satisfactory compromise was arrived at. A conference of ambassadors was assembled in London, and on Dec. 20 the principle of Albanian partial autonomy was admitted. All the Powers agreed to leave to the Great Powers the task of delimitating the frontiers, and among these the status of Albania and a clause was drafted to this effect for insertion in the Treaty of London (May 1913) between the allies and Turkey. On April 7 1913 Sir Edward Grey made the following statement to the House of Commons:—"The agreement between the Powers respecting the frontiers of Albania was reached after a long and laborious diplomatic effort. It was decided that the littoral and Scutari should be Albanian,
while Ipek, Prizen, Dibra and (after much negotiation) Jakova should be excluded from Albania. This arrangement leaves a large tract of territory to be divided between Serbia and Montenegro; the fruits of victory.

"It is to be borne in mind that in making that agreement," Sir Edward Grey added in answer to a question "the primary essential was to preserve agreement between the Powers themselves." The natural rights of Albania were accordingly sacrificed for the sake of the general peace of Europe.

In pursuance of this decision two international commissions proceeded to Albania, the one to delimitate the northern and north-eastern, the other the southern frontiers. The duties of the first were largely of a technical character, since with the exception of two or three small gaps the ambassadors had themselves traced the frontiers. However, never called upon to report. Thus half a million Albanians forming a compact ethnographical unit within the watershed which constitutes the natural geographical boundary of Albania were left without appeal to Montenegro and Serbia. The southern commission was given wider powers. Under the chairmanship of Lt.-Col. Doughty Wylie the work was undertaken conscientiously, and resulted in the drawing of a frontier which may be considered in the circumstances a fair balance of conflicting ethnographical, geographical and economic claims.

Rule of William of Wied — Meanwhile the status of Albania was defined by the ambassadors. On July 29, 1913 it was agreed to recognize her as a sovereign independent state under perpetual neutrality guaranteed by the Powers. A foreign prince was to be chosen as ruler. Dutch officers were commissioned for the organization of an Albanian gendarmerie and an international commission of control was instituted, composed of one delegate from each Power and one Albanian representative, with authority for ten years to control the finances of the new State and to check the Albanian Government when acting beyond the limits of its jurisdiction.

On account of the mutual jealousies of the Powers, and especially those of Italy and Austria-Hungary, it had become impossible to choose for prince any man of known purpose or courage. Prince Charles of Rumania and the Duke de Montpensier were among the able candidates turned down. Ahmet Fuad Pasha of Egypt was suggested but Ismael Kemal let it be clearly understood that Albania intended to become a European State, and would not accept an Eastern ruler. The choice eventually fell upon Prince William of Wied.

When the international commission of control assumed the sovereignty of Albania at the request of Ismael Kemal in Jan., 1914, pending the arrival of the prince, the number of governments ruling over the several provinces was three. First in priority was the Provisional Government of Ismael Kemal at Valona. The second was the international administration of Scutari, with Gen. Phillips in command. The third was the Government of Essad Pasha in central Albania. This adventurer, after bringing about the murder, so it seems, of the Turkish commander defending Scutari, had betrayed the city in April 1913 into the hands of the Montenegrins on condition of being allowed to march out at the head of his armed followers. These he kept in hand, and on the withdrawal of the Serbs from central Albania he profited by the general discontent with the slow-moving over-cautious Government of Valona to establish a government under his personal direction at Tirana. Meantime the Montenegrins had been persuaded by the Powers to evacuate Scutari and only the Greeks in the south remained in occupation of Albanian territory within the new frontiers.

Essad reluctantly consented to hand over the reins to the international commission of control on the condition that he himself might head the deputation to Neuwied for the purpose of offering the crown to Prince William. He continued, however, to intrigue against his chief, who bestowed upon him after his arrival at Durazzo (on March 7, 1914) the post of Minister of War. The general situation was at this time exceedingly confused. The country was rife with dissension due to the endless delays before the choice and arrival of the Mpret, to the intricate cross-currents of intrigue of Essad, Austria and Italy, and to the ghastly terror that the Greek irregulars secret support but officially repudiated by the Greek Government constituted in the south. Only a bold man capable of striking the imagination of his people could hope to succeed in these circumstances. Prince William, who even before his arrival had alienated the sympathy of many for having laid himself open to suspicion as implicated in the Austrian plots, revealed himself before long a man of neither courage nor resolution. He remained at Durazzo under the guns of Italian and Austrian warships, chiefly occupying himself in making and unmaking his Cabinet.

In the meantime Essad, who had the goodwill of the Italians, continued to intrigue with the object of discarding the Prince, while the Austrians and the Bulgarians were encouraged by Wied plotted with equal pertinacity for the overthrow of the powerful Minister of War. The mistakes of the Prince were at first entirely ascribed by the populace to Essad's machinations. As a result, during the night of May 19, a group of armed Nationalists surrounded his house and Prince William's Austrian guns were trained upon it. Essad's life was only saved by the courageous intervention of an Italian officer. He was eventually placed upon an Italian warship and transported to Italy. Immediately after his departure rebellion broke out among his followers at Tirana. It might easily have been crushed, for Essad's followers, though well armed, were limited to a few thousand men and were detested by the vast majority of the people. But Prince William at first hesitated, then blundered by bombarding the perfectly inoffensive village of Shyak (Shyak), which raised the whole immediate countryside in revolt, and finally lost all caste in the eyes of the Albanians by ignominiously taking refuge during an abortive attack by the insurgents on board a man-of-war. He was never again likely to win the goodwill of his people. When the World War broke out in Aug., 1914, he was still closely besieged in Durazzo. On Sept. 3 he abandoned the country.

The World War — The history after the outbreak of the World War may be very briefly told. Essad returned to Durazzo, and with the help of his friends the Serbs was able for a short time to re-establish his rule in central Albania. The international occupation of Scutari was followed by a Serbian occupation. The Greeks took possession of the south until the advent of the Italians in 1915. The rest of the country fell under the authority of local chiefs. Essad remained faithful to his plan which fore-shadowed the partition of his country between the Serbs, the Greeks, and himself, under Italian protection. In the absence of any authoritative Albanian Government he succeeded for a time in imposing upon the Entente Powers the notion that he represented the will of his countrymen. It was owing to this fact that the articles relating to Albania in the Pact of London were admitted and it is these articles which have given rise to grave difficulties attendant on the settlement of the country since the Armistice of 1918. The articles in question run as follows:—

Article 6. — Italy shall receive full sovereignty over Valona, the island of Susseno and surrounding territory of sufficient extent to assure defence of these points (from the Vojano to the N. and E. approximately to the N. boundary of the district of Chimara on the S.).

Article 7. — Should Italy obtain the Trentino and Istriá in accordance with the provisions of Article 4, together with Dalmatia and the Adria ita, within the limits specified in Article 5, and the Bay of Valona (Article 6), and if the central portion of Albania is reserved for the establishment of a small autonomous neutralized State, Italy shall not oppose the division of S. Albania between Greece and Serbia, should France, Great Britain and Russia so desire. The coast from the S. boundary of the Italian territory of Valona (see Article 6) up to Cape Stylos shall be neutralised.

Italy shall be charged with the representation of the State of Albania in its relations with foreign powers. Italy agrees moreover to leave sufficient territory in any event to the E. of Albania to ensure the existence of a frontier line between Greece and Serbia to the W. of Lake Ochrida.
In Nov. 1916 the Italians had occupied Valona. In the autumn of 1915 the Austro-Hungarians, after overwhelming Serbia; occupied northern and central Albania. Essad retired to Salonika where he continued to pose for some considerable time as the true Albanian representative until he became finally discredited. Many Albanians adhered to the cause of the central emperors. This was not unnatural since a victory for Germany would in all probability have given Albania an autonomous, if not an independent, government within wider frontiers than she could ever otherwise hope for. Under Bairam Tauri, an unexpressed guerrillas, Albanian bands harassed the Allied lines of communication which ran from Santi Quaranta to Koritsa and Salona.

On June 3 1917 Italy proclaimed the independence of all Albania under Italian protection. This proclamation was subsequently explained as not denoting a "prosectorate," but it could hardly be interpreted as anything but a formal repudiation of the articles of the Pact of London. The French, who had occupied the Ersek-Koritsa road, replied by proclaiming the republic of Koritsa. After three months the republic was abolished, but the district remained under French rule until May 1921 when it was handed over to the Albanians. Then came the retreat of the Austrians in the autumn of that year. Thus the greater part of Albania fell under the occupation of Italy. An inter-Allied contingent on the other hand occupied Scutari, while Serbian troops seized Mt. Tarabosh and advanced their line considerabiy west of the 1913 frontier.

In March 1920 the inter-Allied command at Scutari handed over their powers to a small Italian contingent, which in May 1921 still remained in the town as representing the Allied and Associated Powers pending the formal recognition of the Albanian State and the confirmation of its frontiers. Meanwhile important events had occurred which finally paved the way for the reestablishment of Albanian independence. The Italians permitted the formation of a new national provisional government within its area of occupation, and Albania's case was duly presented at the Peace Conference in 1919. Her representatives included Turchan Pasha, who had acted as Prince William's prime minister; Dr. Tourtuli of Koritsa, the eminent specialist in tropical diseases; Mgr. Buncil, Bishop of Alessio; and Mehmet Bey Konitza, later Minister of Foreign Affairs and representative of the Vatra, an important national society of Albanians resident in America which had risen during the past ten years. The inter-Allied command of Field-Kommandant Mgr. Fa Noli, to take a leading part in the cause of Albanian independence. The general complications of the Adriatic question, however, prevented the Albanian case being concluded. President Wilson vetoed a proposal to partition the country. The Italians at the same time lost their initial popularity. It was generally understood that they had provisionally accepted a mandate for Albania. There were evident signs in any case of an intention on their part to remain in permanent occupation. They treated the local authorities with scant courtesy and seriously hampered the independent working of the central Government. The latter were also keenly aware that a permanent Italian occupation inevitably entailed the admission of at least part of the Greek and Serbian claims to their territory.

It was in these circumstances that fighting broke out between Albanian irregulars and the Italian troops, which had been greatly reduced in numbers and were suffering badly from malaria. The Italians accordingly concentrated within certain strategic areas, and thus enabled a new and more representative Albanian Government to be formed in Feb. 1920, first at Lazar and then at Tiran, under the presidency of Sulaiman Bey Delivina. Four constitutional regents were simultaneously appointed, namely, Mgr. Buncil, Dr. Tourtuli, Abdi Topcani and Akif Pasha—i.e. two Mussulmans, one Catholic and one Orthodox. Later in the year the Albanians under Bairam Tauri again attacked the Italians, capturing many important positions and pressing them hard within the Valona area itself. Italy was in no mood for further wars. The economic and social condition of the country forbade any hope the Italian Nationalist parties still entertained of imposing by force of arms Italian rule in Albania. Moreover, Glottati had assumed power with a large Liberal majority behind him, and he had made up his mind to tackle the Albanian question otherwise. The result was an agreement signed on Aug. 2 1920, by which Albania's independence was completely recognized by Italy and the evacuation of the country by the Italian troops assured.

The Serbs, who had attempted to profit by the occasion, had advanced on Tiranu, but after some severe fighting had been driven back to their original positions. Yet in spite of these successes the government of Sulaiman Bey fell in the autumn. It was replaced by a Ministry under Illias Vroioni, pending the election due to take place in the following spring of a new Chamber, Mgr. Fa Noli was appointed Albanian representative at Geneva and in Jan. 1921 Albania was formally admitted to full membership of the League of Nations, all the parts (Italy, Serbia and Greece), at one time interested in her dismemberment, recording their vote in favour of the motion.

ALBERT, DUKE—ALBERTA

The urban pop. amounted in 1916 to 188,749 and the rural to 307,776. There were 119,510 families inhabiting 113,347 dwellings, the average number in the family being 4.15. The origins of the people were as follows:—Canadian-born 241,357; English 76,068; Irish 36,420; Scotch 47,494; Welsh, etc., 1,500; French 17,679; German 12,485; Austro-Hungarian 11,688; Scandinavian 6,825; Dutch 2,465; Italian 14,118; Polish 1,791; Russian 6,422; Belgian 3,026; Lithuanian 1,050. Of S. immigrants of all nationalities born in the United States there were 91,674, almost precisely 50% of them being of British descent.

Edmonton is the capital, with a pop. estimated in 1920 at 60,000 (24,000 in 1911). It is beautifully situated on the N. bank of the North Saskatchewan on a table-land overlooking and 200 ft. above the river. It is the seat of the university of Alberta, and a popular residential district. Fort Saskatchewan, Vegreville, and Vermilion are thriving trading towns on the Canadian National railway.

The busy city of the southern district, and the principal business section of the province, is situated in the valley of the Bow river. It had in 1920 a pop. estimated at 75,000 while in 1911 the pop. was 43,794. It is on the main line of the C.P.R. and the lines of the Canadian National railway. The manufacturing establishments include meat-packmg plants, flour mills, lumber mills, brick and cement works. It is the door to the magnificent scenery of the Rockies, and the great number of summer tourists has necessitated the building of large modern hotels.

Medicine Hat had in 1920 an estimated pop. of 10,000, and is one of the best of the oil centres. It is one of the large flour-milling centres and is known as the natural-gas city, having been supplied with natural gas from the time of its inception. Bricks and drain pipes are extensively manufactured.

The pop. of Lethbridge was estimated at 10,000. It is a thriving coal-mining, agricultural and railway centre, and is an important sheep station.

The Legislative Assembly of Alberta consists of 58 members, with an Executive Council composed of eight members chosen from the Legislative. The province is represented in the Dominion Parliament by 12 members in the House of Commons and six Senators.

High schools have been opened at all the leading centres, and normal schools for the training of teachers are in operation at Calgary and Camrose. The province owns 250 ac. of land at Edmonton, where a well-equipped university has been established. Alberta College, a Methodist theological training school, a Presbyterian theological training college, and other denominational institutions are affiliated with the university.

Technical schools are established at Edmonton, Calgary, and Medicine Hat. Schools of agriculture are established at different points and there are nine demonstration farms; the university has a faculty of agriculture.

Agriculture.—Until the end of the 19th century southern Alberta was regarded as only fit for ranching, but in 1902 the first irrigation scheme was undertaken. At that date its chief products were wheat and saskatoons. Since then irrigation projects have been undertaken, and a large area of land is now farmed with the help of the water thus made available. The area of the land under cultivation by irrigation in 1920 was up to a total of nearly 3,000,000 ac. of which 50% is actually irrigable land. The benefits of irrigation have been well demonstrated in southern Alberta. Besides making it possible to grow sugar and beet products and hay crops, irrigation has enabled more land to be brought under cultivation. On dry land grain is the characteristic crop. Under irrigation heavy crops of alfalfa and roots are grown, which make profitable stock-raising and stock-feeding possible without the uncertainties and loss which accompany seasons of drought. More stock is raised in southern Alberta now than was raised under ranch conditions. The chief

Alberta (see 1,499).—The pop. of the Canadian province of Alberta in 1916 was 496,525. The increase since 1901 is shown in the following table:—

The poet Verhaeren and the painter Laermans were on friendly terms with the royal family, the latter receiving personal attention from the Queen when he was threatened with the loss of his sight.

On Aug. 2, 1914, when the Germans sent their ultimatum to Belgium, King Albert at once prepared to defend his country. He himself took command of the army. He only left Antwerp at the last possible moment, and then established himself with the army on the Yser. During the whole of the war he remained with the troops, having his headquarters at La Panne, where he was exposed to the risk of enemy bombardments. He made continual visits to the front-line trenches, and even surveyed the enemy's lines from an aeroplane. The Queen remained with him, acting as a nurse at the Hospital near La Panne. She also interested herself deeply in the welfare of the soldiers in the trenches, and superintended the establishment of canteens and aid posts. Prince Leopold, King Albert's elder son, lived by his father's wish the life of a simple soldier in the 12th Regiment.

When the general offensive of Oct. 1918 was undertaken, King Albert was appointed commander of the northern army groups, consisting of both Belgian and French, which captured the forest of Houthulst, the Flandersstellung, Thourout, Ostend and Bruges, and forced the passage of the Lys. On Nov. 13, 1918 the King and Queen made their entry into Ghent, and on Nov. 22 into Brussels, being received with enormous enthusiasm. Even before the signing of the Armistice the King had summoned to Lophem a number of politicians, and arranged a new Government containing representatives of the three more important Belgian political parties.

After the Armistice the King occupied himself actively with the improvement of conditions in his country, visiting the devastated areas, and contributing considerable sums to "King Albert's Fund," which was devoted to providing temporary shelter for sufferers from the war. He also undertook journeys to Brazil, Spain, France, the United States and England, with the object of studying trade conditions and finding new outlets for Belgian commerce. The popularity of the King and Queen, great even before the war, steadily increased, even the Socialist party taking many opportunities of expressing feelings of respect towards the royal family. King Albert declined the augmentation of his civil list which was offered to him by the Chamber immediately after the war.

Mathys, Prince Albert; Mousseau, Le Prince Albert au Congo; La mort de Leopold II. et l'Avènement du Roi Albert (Recueil de Documents, 1909); Roux, Le Roi Albert; Percy, The Life Story of Albert I., King of the Belgians (1914); MacDonnel (John de Courcy), The Life of H.R.H. Albert (1915) and Belgium: her Kings, Kingdom and People (1914). (J. P.)

ALBERT, DUKE OF WÜRTTEMBERG (1865—), German general, the son of Duke Philip of Württemberg, was born in Vienna on Dec. 23, 1805. As the King and Queen of Württemberg had no male heir, he was as soon asagnate the heir presumptive to the Württemberg throne. He passed through the different grades of a military career and was appointed general in command of the XI. Army Corps at Cassel in 1866 and in 1868 was entrusted with the command of the Württemberg Army Corps. In 1915 he was advanced to the rank of Generaloberst (colonel-general, immediately below field-marshal) and was appointed Inspector-General of the 6th Army Inspection. At the outbreak of the War he took over the leadership of the 4th Army on the western front, was advanced to the rank of field-marshal-general in 1916 and appointed chief-in-command of the group of armies on the front in Alsace-Lorraine, which fought under his leadership till the end of the war. Since then he has lived as a private citizen on his Württemberg estates. He married in 1894 the late Archduchess Margarete Sophie of Austria, the sister of the Archduke Francis Ferdinand who was assassinated at Sarajevo.

Natural gas under heavy pressure is found at many points throughout the province and is extensively used for power, fuel and light. In the Athabasca region and near the B.C. boundary there are de­cided indications of petroleum and a limited amount of coal oil is being produced. Alberta possesses many important mineral resources, but it is difficult to estimate the total value of these resources. The province is a large producer of oil and gas, and the production of these products has increased steadily in recent years.

In the northern part of the province, the land is characterized by rolling hills and low mountains, with a mixture of hardwoods and coniferous trees. The climate is cold, with long winters and short summers. The province is a major producer of timber, with forests covering about 12 million hectares. The province is also a major producer of pulp and paper.

The economy of the province is based on agriculture, forestry, and resource extraction. The province is a major producer of oil and gas, as well as a major producer of coal. The province is also a major producer of lumber and forest products.

The province is also a major producer of electricity, with a large number of hydroelectric power stations. The province is a major producer of livestock, with a large number of cattle, sheep, and goats. The province is also a major producer of dairy products.

The province is also a major producer of minerals, with significant deposits of coal, gold, and silver. The province is also a major producer of uranium and other minerals.

The province is also a major producer of energy, with a large number of power stations. The province is also a major producer of transportation services, with a large number of roads and highways. The province is also a major producer of tourism, with a large number of attractions and activities.

The province is also a major producer of education, with a large number of schools and universities. The province is also a major producer of health care, with a large number of hospitals and clinics. The province is also a major producer of culture, with a large number of museums and art galleries.
and lighting; but use in large quantities, or in manufacture, was only possible under special authority and under excise supervision. The Netherlands legalized the use of denatured alcohol in 1865; in 1872 France permitted its use under a special tax, and in Germany its employment was authorized in 1879, the other European countries following, Austria in 1888, Italy in 1889, Sweden in 1890, Norway in 1891, Switzerland in 1893, and Belgium in 1896. In the United States the tax on distilled spirits was repealed in 1857, but was re-imposed at the outbreak of the Civil War in 1861, and it was not until 1907 that denatured alcohol became tax-free for general purposes. Alcohol was used in Germany for many years before the World War in increasing quantities as a source of heat, but its application for light and power started about 1887. In 1893, in order to bring down its price, a distillation tax was imposed, from which a refund was paid on alcohol used for other than beverage purposes. About this date the output of alcohol in Germany and its use in stationary internal-combustion engines increased rapidly. The chief source was the bounty-fed potato, and the industry was an agricultural one worked on cooperative principles.

The first competition in connexion with alcohol as a fuel for motor vehicles took place in France in 1901, followed in the next year by Germany, and in 1904 by Belgium, with the employment for this purpose did not make much headway. The subject received little attention in the United Kingdom, owing to the relatively high cost of home-produced alcohol as compared with that of imported petrol; and the use of alcohol in England for generating mechanical power was never contemplated nor provided for by the Legislature before 1920, when, as the result of the consideration of the position by the Government, following on a report by a Departmental Committee appointed towards the end of 1918, clauses were inserted in the Finance Act 1920 legalizing the use of alcohol for power purposes.

Whilst alcohol is not in many respects so similar to petrol, its vapour mixed with a proper proportion of air being drawn into the cylinder where it is compressed and ignited, it cannot be used with maximum efficiency by itself in engines, such as are fitted to modern motors because it requires a higher degree of compression than petrol engines are usually designed to stand, and also because, unless special arrangements are made, a motor engine will not start readily from the cold with alcohol alone. For these reasons alcohol has not been used to any extent in petrol motors. Mixing with benzol and/or petrol, or with ether in varying proportions, enables it, however, to be employed successfully in them, until such time as engines specially designed for it are manufactured.

In the event of its production being a commercial possibility it should, therefore, form a valuable addition to the liquid-fuel resources of the world (see FUEL).

In the appended table are given some comparative figures in connexion with commercial petroleums and alcohol, taken from H. R. Ricardo's paper on "The Influence of Various Fuels on the Performance of Internal-Combustion Engines," published in 1921.

The lower calorific value plus the latent heat of evaporation at constant volume.

Alcohol is produced by fermentation from vegetable substances containing starch or sugar, from fermentable sugar made by the hydrolysis of cellulosic bodies, and synthetically from calcium carbide and from the ethylene contained in coal and coke-oven gases. These vegetable substances may be divided into foodstuffs and non-foodstuffs. If foodstuffs are to be employed it must be possible to grow them in excess of food requirements, and at a cost low enough to ensure that the price of the alkohol shall be about the same as that of other liquid fuels. Foodstuffs could not be grown in the United Kingdom at sufficiently low prices, nor in sufficient quantities, to produce alcohol commercially and on a large scale.

Regulations started in 1920 by the British Government, in connexion with the prevalence of alcohol fumes in the British Empire, have shown, however, that there are large areas of suitable land in the British Empire where the cost of production would be comparatively low. It is considered that it may be possible to obtain alcohol in excess of food requirements, and in sufficient quantities to produce alcohol for local consumption to replace expensive petrol. It is in this direction, which is being actively followed up in the dominions and colonies, that the production of alcohol for internal-combustion engines is most likely to advance so far as the British Empire is concerned.

As a source of non-foodstuffs, or cellulosic materials, such as grasses, reeds, straw, peat, waste wood, sawdust, etc., is not yet possible, for, although research work is in progress to discover a process that could be worked on a commercial basis in those regions where such materials exist in sufficient abundance, it has not yet produced any definite results. It would appear, however, that the production of alcohol within the British Empire from waste materials, which can be collected and treated at low cost, offers the best chance of the production of alcohol to the United Kingdom of an alternative liquid fuel for internal-combustion engines.

Its manufacture from carbide is only possible where very cheap power is available, and its conversion from the quantities of ethylene derived from coal and coke-oven gases is too costly to be worked out, is not likely to add very materially to the world’s liquid-fuel supplies.

The use of alcohol for power purposes, mainly in connexion with stationary and agricultural engines, was common in Germany before the war, its employment in Europe and also in the United States for motor engines has not made much headway, nor was it attempted in England before 1921 though the idea was first suggested to the British Empire to develop it for the purpose on any considerable scale. In France, where large stocks of alcohol were left over from the manufacture of explosives during the war, it was unable to compete with petrol at the petrol prices, and was only being used in comparatively small quantities, and mixed with benzol. The German production of alcohol had fallen off very much since the war, and little alcohol was being used for motors, benzol being the fuel principally employed. The alcohol was derived from the sulphite liquors of the wood-pulp industry was contemplated, but carbide, although produced in increasing quantities, was not considered as a possibility with its materials going to the fertilizer industry. An alcohol monopoly law was passed in July 1918. With cheap water-power Switzerland has considerable capacity for producing carbide and alcohol from it, but even in that country the ultimate cost of alcohol made in this way was so high that its production after the war had not paid. In Sweden, where wood pulp is made in enormous quantities, the manufacture of alcohol from the waste sulphite liquors is carried on, and it was estimated that about 800,000 gal; the actual production, however, amounted to about 2,750,000 gal only. Norway also produces sulphite liquors and alcohol from them on a small scale.

There are several distilleries in the United States devoted to the production of industrial alcohol, with an estimated capacity of about 90,000,000 gal; in 1919 about 100,000,000 gal were made, representing, however, only about 2.5% of the estimated United States liquid-fuel requirements for 1920. Some attention is also being given to the manufacture of alcohol for power purposes in Hawaii, Porto Rico and the Philippines; and in Cala, from the molasses produced as a by-product in the sugar refineries.

ALDEN HENRY MILLS (1836–1910), American editor, descendant of John Alden, was born at Mt. Tabor, Vt., Nov. 11 1836. After graduating from Williams College (1857), under the régime of Mark Hopkins, he completed the course at the Andover Theological Seminary (1860); but he never took orders. He first contributed to the Atlantic Monthly two essays on "The Eleusinia" (1859–60), and then a paper on "Pericles and President Lincoln" (1863). These fruits of his classical studies show the influence of De Quincey, who was the subject of another essay in the Atlantic (1863). He delivered twelve lectures, and before the Legislature, "The Structure of Paganism." He was managing editor of Harper’s Weekly from 1865 to 1869, and then became editor of Harper's Magazine, which position he held until his death in New York, Oct. 6 1919.

He was author of God in His World (1890); A Study of Death (1895) and Magazine Writing and the New Literature (1908).

ALDRICH, NELSON WILMARTH (1841–1913), American politician (see i.356), died in New York April 16 1915. While chairman of the National Monetary Commission, he pro-
posed, in 1911, far-reaching changes in the banking laws of the United States with a view to the creation of central reserves, a system afterwards adopted in the Federal Reserve banks. He retired from the U.S. Senate in 1911, after 30 years' service.

ALEXANDER, King of the Hellenes (1803-1920), second son of King Constantine and Queen Sophia, was born Aug. 1, 1803, and ascended the throne of Greece, June 12, 1917, on the deethronement of his father by the Anglo-French forces during the World War (see CONSTANTINE). He, not unnaturally, looked upon his position at first as a mere temporary arrangement. The Government itself was meanwhile in the responsible hands of Venizelos, who had the confidence of the Allies. But the defeat of Germany, and Venizelos's diplomatic triumphs at the Peace Conference, seemed to breathe a new spirit into the young King. From the day of his triumphal entry into Athens, he evidently took a more active personal interest in the prospect of being the ruler of Greater Greece. This change in his attitude was indeed so marked that his royal parents in exile in Switzerland were said to be greatly disconcerted; but it gave him an entirely new popular interest among the people. His sudden death on Oct. 27, 1920, by blood-poisoning from the bite of a pet monkey, put a sudden end to all such expectations, and it seriously disarranged Venizelos's plans. King Alexander was buried amid widespread demonstrations of popular grief; but a fortnight later, in the general election, the Venizelist party was defeated. It is practically certain that, could this election have been postponed for a few months and a suitable successor to the throne found, King Constantine would never have been able to return, as he did, to Greece. But postponement was impossible after Venizelos's pledge to the Greek people; and, in the absence of any other serious candidate for the Greek throne, the old sympathies for Constantine won the day.

In Nov. 1919 King Alexander had insisted, against the advice of Venizelos, on making a morganatic marriage with a beautiful young Athenian lady, Aspasia Mano; and after his death a daughter was born to her in Paris on March 25, 1921.

ALEXANDER 1, King of the Serbs, Croats and Slovenes (1888—), was born at Cettinje on Dec. 4, 1888, the second son of Prince Peter Karadjorjević (later King of Serbia), and of Zorka, third daughter of Prince Nicholas of Montenegro. His mother died in 1890, and during his early years he of course shared the exile of his father, who lived at Geneva. In 1899 he was sent to be educated at St. Petersburg, and in 1904 entered the corps des pages at the Tsar's court. It was not till 1906 (nearly six years after his father's election to the Serbian throne, in succession to the murdered King Alexander Obrenović) that the young prince came to reside permanently in Serbia. Soon after his return his elder brother, Prince George, was obliged to renounce the succession (March 1909), owing to his unbalanced temperament and various incidents that occurred during the Bosnian crisis; and Alexander was thereupon formally recognized as crown prince. On the outbreak of the Balkan War he assumed nominal command of the First Army, and won his spurs at the battle of Kumanovo, subsequently serving with distinction throughout the campaigns against Turkey and Bulgaria. On June 24 1914 King Peter, whose health had completely broken down, appointed him as prince regent, and he thus held the position of commander-in-chief when the World War broke out. He remained permanently at army headquarters, and shared with his soldiers all the privations of the retreat through Albania. On reaching the coast he fell ill and underwent a serious operation, when, as the story goes, the convalescent resolutely declined the proffered assistance of an Italian doctor. When the prince had recovered, it was found necessary to convey him across the Adriatic; he remained till all the refugees had been transported into safety, and eventually found his way on foot to Durazzo. After the exiled Serbian Government had established itself at Corfu, Prince Alexander and Mr. Pašić paid visits to Paris and London, where the Prince was received with warm ovations. On April 5 1916, in receiving an important deputation of British sympathizers (led by the Archbishop of Canterbury, the Lord Mayor, Lord Milner and Sir E. Carson), he publicly identified the dynasty with the cause of unity, expressing his conviction that in the final victory "our Yugo-Slav people, united in a single state, will also have their part." During the rest of the war he remained at Serbian headquarters, and shared his army's victorious advance in Oct. 1918. On Dec. 7 delegates of the Yugo-Slav National Council in Zagreb forswore King Alexander and organized him as 'the last ruler of all Belgrade and the former dual monarchy, and he assumed the title of "Prince-Regent of the Serbs, Croats and Slovenes." The attempt made upon his life on June 28 1921, after he had taken oath to the new Yugo-Slav constitution, was the outcome not of any personal unpopularity, but of the subversive aims of the Communists and other revolutionary groups, who hoped to create confusion in the new state, owing to the lack of a direct heir to the throne. On Aug. 16 1921 Prince Alexander succeeded his father as King of Yugoslavia.

ALEXANDER, BOYD (1873-1910), British soldier and explorer, was born at Cranbrook, Kent, Jan. 16 1873. He was educated at Radley, and afterwards entered the army, joining the Rifle Brigade in 1893. In 1897 he led a scientific expedition to the Cape Verde Is., and in 1898 went on his first African journey to the Zambezi and Kafuk rivers. He was appointed to the Gold Coast constabulary in 1900, and took part in the relief of Kumasi. In 1904 he led a scientific expedition to Fernando Po, where he ascended Mt. St. Isabel and discovered various new species of birds. The same year saw the commencement of his most important work—the Alexander-Goulding expedition across Africa from the Niger to the Nile, which occupied three years. During this period he surveyed the shores of Lake Chad and explored a considerable part of eastern Nigeria, returning to England by way of the rivers Ubangi, Shari and Nile. For his various discoveries he received gold medals from the Royal Geographical Societies of London and Antwerp, besides honours from other learned societies. He returned to Africa in 1908, and was killed by natives at Nyeri, in Wadai, April 2 1910. Alexander published From the Niger to the Nile (1907), besides many articles and papers in scientific and geographical periodicals.

See Herbert Alexander, Boyd Alexander's Last Journey, with a memoir (1912).

ALEXANDER, SIR GEORGE (1858-1918), English actor (see r. 564), died at Chorleywood, Herts., March 16, 1918. He was knighted in 1911. Among his later productions at the St. James's theatre were R. S. Hichens's and J. B. Fagan's Bella Donna; Piner's The Big Drum and Louis N. Parker's The Aristocrat in this he made his last appearance together with the veteran actress Genevieve Ward.

ALEXANDER, JOHN WHITE (1856-1915), American painter (see r. 564), died in New York June 1, 1915. He received a first-class medal from the Carnegie Institute, Pittsburgh, in 1911, and a medal of honour at the Panama-Pacific Exposition in 1915. He had been president of the National Academy of Design since 1909.

ALEXANDER, WILLIAM (1824-1911), Protestant Archbishop of Armagh and primate of All Ireland (see r. 565), who resigned his see Jan. 30, 1911, and was created G.C.V.O., died at Torquay Sept. 12, 1911.

ALEXEYEV, MIKAIL (1837-1918), Russian general, was born in 1837, and entered the army in 1876. He completed his studies at the General Staff College in 1890, and joined the Russian General Staff. In 1904 he became a general. He took part in the war with Turkey in 1877-8. During the Russo-Japanese War he was the director of the operations on the staff of the II. Army. After further staff service he became in 1912 commander of the N. Caucasian army Corps. At the outbreak of the World War he was the nominated chief of the staff of the south-western front. The first operations were skilfully carried on by him, and the great Russian victory in Galicia in 1914 was his work. In March 1915 he was called to command the group of armies of the north-western front. A stupendous task awaited him here; eight armies were confided to him, but these masses were destitute of all means of combat. The events in Galicia in April 1915 had their repercussion further north, where the position became desperate, and the army seemed lost. But by the end of Aug. the armies
were saved, thanks to the energy and ability of their commander. In Aug. 1913 he was nominated chief of the headquarters of the supreme command, and worked there with the Emperor, who had just assumed the supreme command. He served in this capacity during the successful campaign of 1916, until in Nov. a breakdown of health compelled him to give up his office. After the revolution of March 1917 he became commander-in-chief, but in May 1917 he was dismissed. Recalled by Kerensky in Sept., he remained at headquarters for 12 days in order to exercise a steady influence during the conflict between Kornilov and Kerensky, and then left, being unable to work with men who he considered had brought misfortune and shame on his country. At the commencement of the Bolshevik régime he went to the south of Russia, where he soon became the leader of the “Volunteer Army,” and took the field against the Bolsheviks. He died of heart disease Oct. 10, 1918.

ALGERIA (see 1,642).—The figures of the 1911 census showed a total pop. for Algeria of 5,492,569, of whom 732,943 were Europeans. Of these 35,572 were French, 13,746 Spaniards, concentrated especially in the department of Oran, and 36,661 Italians, in the region of Constantine.

The administration of the country was still in 1917 in the hands of a governor-general residing at Algiers, as supreme head of all the civil services, with the exception of the non-Musulman services of justice, worship, public instruction, treasury and customs, which remained attached to the French ministerial department. The governor-general has to assist him a general secretary and a Government council. Since 1900 Algeria has enjoyed a large measure of budgetary autonomy. The governor-general submits a special budget to the vote of the Algerian representative assemblies, or the financial delegations which were created in 1898. The delegations are divided into three sections, one of which represents colonists, another non-colonising taxpayers, and the third native Musulmans. The budget, when voted by the financial delegations, is submitted to the French Parliament. The estimates for 1922, comprising both ordinary and extraordinary revenue and expenditure, amounted to 355,000,000 francs.

The northern portion of the territory is administered under two systems, one civil and the other military. In the civil zone the administration is that in force in France. This zone is divided into departments, cedars, Algiers, and Constantine, with prefects, general councils and sub-prefects as in France. Each department elects two deputies and one senator to the French Parliament, only French citizens having the right to vote. The military zone is divided into three administrative regions, under the control, subject to the governor-general, of generals of division. These regions are cut up again into sectors administered by officers of the Department for Native Affairs. In accordance with the composition of the population, three methods of local administration are employed. In the “full” communes there are municipal councils, elected by the townspeople; in the “mixed” communes public services are run by an administrator, assisted by a non-elected municipal council; the “native” communes are run by boards of self-assisted of native advisers, who are appointed by the governor-general.

The colonization of Algeria was rendered difficult by the presence of a native population which already had its own civilization, and was nomad and warlike in its instincts. A start was made in the region of the Tell, and then the mountains and high plateau-lands were taken in hand. There has been a spontaneous flow of Italian and Spanish immigration, and a system of frontier concessions to settlers and merchants. Attracted by the large quantities of immigrants from the south of France who have settled down well in the country. Between 1904 and 1914, 266,000 hectares of land had been settled, of which 91,200 were free grants.

Agriculture has made great strides in spite of the difficulty of irrigation. By a judicious system of barrages and canals, the torrential rains have been harnessed up and spread over the land. Much has been done, also to fight the locust, and to carry out a methodical policy of manuring. The results obtained have been brilliant. In the Tell wheat and wine are grown on a large scale, and indeed Algerian wine has become a serious competitor with French wine. In 1920 Algerians exported 2,729,551 hectolitres of wine, of which 2,418,726 went to France. The crop of cereals, which fluctuates much in consequence of variations in the financial and climatic conditions, was 1,325,000 metric quintals in 1915; 20,200 in 1916; 1,160,180 in 1917, 13 million in 1918, 506 million in 1919. Olive plantations produce 1,442,000 metric quintals, and of these 911,000 quintals are exported. The exports of fruits and vegetables are considerable. Olives and figs are grown in the mountains, and the principal product is olive oil, which has been greatly improved. The exports of this product in 1920 were 46,000 metric quintals, valued at 6,900,000 francs. Cotton is grown in the Oran and Algiers, and great efforts have been made to increase the output of tobacco, of which over 24,000 metric quintals were exported in 1920. Berbera, from which the chaff is collected, is an alfalfa which covers great areas. It is exported in very large quantities to Great Britain, where it is used in the manufacture of good quality paper. The alfa exports in 1916 were 1,979,970 quintals, in 1917 6,304,000, and in 1918, 10,233,000, of which 4,000 metric quintals are destined for France.

Minerals.—The country is rich in minerals, which, however, have not been thoroughly exploited. The chief mineral resource is iron, the exports of which in 1920 amounted to 1,114,438 tons, valued at 33,879,000 francs. There are large phosphate deposits in the Constantine province, which exported 334,704 tons in 1920 to a value of 18,1 million francs. There are also copper, zinc, lead, and antimony mining industries. The deposits of copper are in the south, and the work of British and American prospectors in the Oran indicates the possibility of extraction of oil fields of some size. In 1900, Algeria was a producer of three and a half million metric quintals of petroleum; in 1918, they were brought to 2,225, and many new fields were being considered. The three chief ports handled the following traffic in 1920: Algiers, 6,264,735 tons; Oran, 3,075,626 tons; Bona, 1,105,362 tons. A great deal of coal has been found, having done duty at five generations of French government, and motor-ways have been built from Targit to Timbuktu. An aerial postal service has also been organized.

Commerce.—The general trade in 1920 amounted to 6,324,000,000 francs. Exports to special destination to the value of 1,442,000,000 francs arose from the requirements and production of the colony, amounted to 3,077,000,000 francs, of which 2,535,000,000 francs were imports, and 1,442,000 francs, about 30,000,000 francs. Of the imports of oil, France took respectively 1,083,000 francs, and 1,006,472 francs. These figures show a very large increase, the general trade in 1918 amounting only to 1,529,000,000 francs, and in 1919 to 2,287,900,000 francs. In 1913, the last normal year, the trade was 1,239,000,000 francs. About 1920, 500,000 francs were imports, and 563,000,000 francs were exports. In judging of these figures, the drop in the value of money has to be borne in mind.

Native rights.—The valuable help given by the native population of Algiers to France during the World War led, as it did in other parts of the French colonial empire, to a wider recognition of the political rights of the native. A law was passed, Feb. 4, 1916, by which all native religious, in the army, was a land-owner, farmer, or licensed trader, knew how to read and write French, or was the head of a family. A French citizen is one who does not receive French citizenship, are represented in all the deliberative assemblies by elected members who sit with the same rights as those enjoyed by the French members of such assemblies. With reservations thereto the same has been granted as footing as French citizens. In the beginning of 1919 the special Arab taxes, which were supported by the native population alone, were done away with, and their place was taken by income and property taxes. It was proposed to form an Algerian consulting committee in Paris, in which natives would sit.

(M. R.)

ALLBUTT, SIR THOMAS CLIFFORD (1836– ), English physician, was born at Dewsbury, Yorks., July 20, 1836. He was educated at St. Peter’s, York, and Caen College, Cambridge, where he took a first class in the natural science tripos in 1860. He studied medicine at St. George’s Hospital and afterwards in Paris, subsequently practising in London and Leeds. He carried out many researches on the subject of the generalised convulsions and made important contributions to the subject of tetanus and hydrophobia. He also devoted much time to the study of ophthalmology, and was the inventor of the short clinical therometer. He was consulting physician to many institutions, and from 1889 to 1892 was a commissioner in lunacy. In 1892 he became Regius professor of physic at Cambridge, and in 1907 was created K.C.B. Sir Clifford Allbutt was a member of many Government committees, including the Home Office inquiry into trade diseases, and during the World War he was an hon. colonel in the R.A.M.C.

His published works include The Ophthalmoscope in Medicine (1871); On Sorensen (1885); Diseases of the Heart (Lancet lectures, 1896); Historical Relations of Medicine and Surgery (1906); Greek Medicine in Rome (Fitzpatrick lectures, 1909–10); Diseases of the Arteries and Angina Pectoris (1913) and Science in the School
ALLEN, SIR J.—ALLENBY, EDMUND H. H. 113

(1917). He also edited *Systems of Medicine and Gynaecology* (1896, 1899, 1907).

ALLEN, SIR JAMES (1855— ), New Zealand statesman, was born in South Australia Feb. 10 1855, and went to New Zealand about 1858. He was educated at Clifton College and St John's College, Cambridge, where he held a natural science exhibition. At Cambridge he played in the University Rugby football fifteen and took his M.A. degree; and he afterwards studied at the Royal School of Mines and won the Bessemer and de la Beche medal. In 1887 he made a remarkable entry into politics by winning the Dunedin East seat from Sir Robert Stout, then Premier and Liberal leader, by 19 votes. Losing this seat at the general election of 1890, he re

ALLENBY, EDMUND HENRY HYNDMAN ALLENBY, 1ST VISC. (1861— ), British field marshal, son of Hyndman Allenby, was born April 23 1861, and joined the Intimilling. Troops in 1880. He served in the army went west in South Africa, where he took part in the BechuanaLand expedition of 1884—5 and in the Zululand operations of 1888. After returning to England with his regiment he passed through the Staff College and in 1860 he married Adelaide Mabel Chapman. He went out to South Africa again as a squadron leader in 1890 and took part in the important cavalry operations by which Kimberley was relieved, in the battle of Paardeberg, and in Lord Roberts's advance to Pretoria and the eastern Transvaal. During the later phases of the South African War he made a great name for himself as a column commander, and he was for his services promoted brevet-lieutenant-colonel and colonel and given the C.B. He then commanded the 3rd Lancers from 1902—5 and for the next four years he was at the head of a cavalry brigade, being promoted major-general in 1909. He became inspector of cavalry in 1910 and, as holding that position, went out to France with the Expeditionary Force in 1914 in charge of the cavalry division.

The work of his mounted troops during the retreat from Mons, the subsequent advance to the Aisne, and the first battle of Ypres won great praise, and on a second cavalry division arriving Allenby was appointed commander of the newly est. Cavalry Corps. He was about the same time given the K.C.B. In June 1915 he was transferred from this to the command of the 5th Army Corps; but he held that position for only a short time as, in the following Oct. on Gen. Monro's proceeding to the Near East, he succeeded that general as chief of the 3rd Army, which he led for nearly two years. His army was not called upon to undertake operations on any large scale during 1916, but it shared to some extent in the later stages of the battle of the Somme. In 1917, on the other hand, it was very heavily engaged in the Arras region during the spring months and won much valuable ground. Allenby had been promoted lieutenant-general in 1916, and in June 1917 he was selected for the command of the troops in Egypt and Palestine, where elaborate preparations had been made for an offensive campaign; he was at the same time promotedgeneral.

The season was unsuitable for active operations on the borders of the Holy Land for the first three months after his arrival in Egypt, but these were spent in perfecting preparations for an advance, which began at the end of Oct. with the capture of Beersheba and the taking of Gaza a few days after. These successes were followed up relentlessly. Jaffa fell Nov. 17, one of the first victories with loss out of every position that they tried to take up, and, after vain efforts on their part to bar the way to Jerusalem, that city was surrendered Dec. 9. Allenby, who had been given the G.C.M.G. for these achievements, materially improved his position during the next four months, but he was then obliged by events in France to despatch some of his troops to the western theatre of war.

During the summer of 1918 fresh forces from India and Mesopotamia took the place of the troops sent away, and in Sept. the British commander struck with crushing effect. By a sudden advance in great force the Turkish front was broken, the plain of Esdraelon was flooded with mounted men, the infantry moved irresistibly forward and, as the result of a masterly combination of war, the enemy suffered an overwhelming defeat. All arrangements had been made in advance for instantly following up the anticipated victory; within a very few weeks Damascus and Beirut had been occupied, troops had been thrust right up to Aleppo, and not only Palestine but also all Syria were in the hands of the Allies. Allenby's brilliant services were recognized by his being given the G.C.B. and, on the general distribution of honours for the war in 1919, he was presented with a field marshal's baton which was raised to the peerage as Earl Allenby of Megiddo and Felchow. He was at the same time a grant of £50,000.
While engaged in his campaigns of conquest beyond the Egyptian borders Allenby had also been responsible for maintaining order in the Nile delta and for its protection against attack from without, matters that had at times given grounds for anxiety as there was much unrest due to the abnormal situation that existed. In 1919 he was definitely appointed British High Commissioner in Egypt.

ALLENSTEIN-MARIENWERDER, a region composed of districts of the former Prussian provinces of East and West Prussia, in which a plebiscite was taken, under the Treaty of Versailles, on June 11 1920.

Annexed to the Treaty of Versailles in 1898, the region was given to Poland after the Armistice of November 11 1918 in consequence of the decision of the so-called Plebiscitary Commission a High Commission in order of the Treaty which was established at Strasbourg, comprising many departments and many different services. The General Commission of the Republic is directly attached to the prime minister's office, the affairs of the three departments being centralised in the hands of the under-secretary of the presidency.

The first High Commissioner, M. Georges Maringer, was replaced in April 1919 by M. Alexandre Millerand, who went to Strasbourg with extended powers, and the title of General Commissioner. Called in Jan. 1920 to the premiership of France, M. Millerand had as successor M. Gabriel Alpepite, former resident-general for France in Tunis, and ambassador at Madrid.

Administration.—The general lines upon which French legislation was to be introduced were fixed by the law of Oct. 17 1919, concerning the transitional administration of the recovered provinces. This law settles the transitional methods to be applied to administrative, electoral and financial organization. On the other hand, constitutional laws are not dealt with, because they are Post Facto applicable by the reintegration of Alsatia and Lorrainia with France.

The law of Oct. 17 1919 remains in force the legislative arrangements and local regulations (German law or special Alsacia-Lorraine law) until the introduction of French laws shall have been effected. The authority of the military governors of Strasbourg and Metz is subordinated to the civil power. Article 4 of this law lays down in principle that it is for Parliament to decide what temporary measures shall be introduced pending the definitive introduction of French legislation. The same law establishes that the French fiscal system shall gradually be substituted for that of Germany. The electoral system is that of France. The former Alsatia-Lorrainia has been deprived of the civil laws which spread during German rule; for instance, the laws affecting social insurance. In religious matters, the Republican Government has respected the status quo—that is to say, the Concordat is maintained, also the denominational schools.

It is abundantly apparent that the Government is keeping the solemn promise made during the war by French statesmen and generals to the effect that the customs and beliefs of the people would be respected. The mission of the Commissioner-General is extremely delicate. He has departmental responsibility in these three departments unknown in others. He has to determine how, in what length of time, and with what precautions French laws can be successively applied there. In submitting legislation, he has to inform Parliament as to the gravity of the disturbance which changes must make in settled habits and customs, and as to the difficulties accompanying the return to French rule.
A consultative council has been provisionally organized in connection with the High Commission of the Republic. It comprises 53 members, of whom 3 are senators, 6 deputies, 21 local councillors, and 5 named by the decision of the prime minister. This body deliberates and pronounces upon all questions which fall outside the limits of any one public department, and are submitted to it by the Commissioner-General. It is compulsorily consulted on the budget of revenue and expenditure in Alsace-Lorraine and on all proposed modifications of the fiscal system in force; and also on all administrative or economic bills and regulations affecting the combined populations of the three departments. The consultative council is convoked by the Commissioner-General at least four times a year. Thus the Commissioner-General has at hand a body in which the representatives of the different populations can show forth the interests of these latter and, by expert advice, can facilitate the study and solution of questions common to the Haut-Rhin, the Bas-Rhin, and the Moselle. But this body is purely consultative. The Government of the Republic keeps its power of initiative and its responsibilities; Parliament retains the sovereign power.

**Population.**—The recovered departments are administered like the other French departments. The department of the Bas-Rhin (préfecture Strasbourg) includes 8 arrondissements: Strasbourg-Ville, Strasbourg-Campagne; Erstein-Haguenau; Mulhouse-Sélestat; Wissembourg-Saverne. Its superficial area is 4780.37 square kilometres. There are 561 communes. The pop. numbers 608,116. The department of the Haut-Rhin (préfecture Colmar) includes 6 arrondissements: Altkirch-Colmar; Guebwiller-Mulhouse; Ribeauvillé-Thann. Area 3,957.3 sq. km.; 386 communes; pop. 430,988. The department of the Moselle (préfecture Metz) includes 9 arrondissements: Moselle-Ville; Moselle-Campagne; Boulay-Château-Salins; Forbach; Sarrebourg; Sarreguemines-Thionville; Oestrich-Winkel. Area 6,227.8 sq. km.; 738 communes; pop. 534,445. The combined population, according to the census of March 1911 is, therefore, 1,593,549, as against 1,874,124 at the time of the last German census in 1910.

The falling-off in the number of the population can be attributed in the first place to the war. Alsace and Lorraine had lost in dead and missing about 45,000 men. Moreover, malt-tax Germany kept in the three departments no less than 82,276 soldiers. The German and Austro-Hungarian subjects domiciled in Alsace and in Lorraine before the war numbered 301,764. The number of German civilians who had left Alsace and Lorraine and the Armistice up to April 1921 was 76,467. These departures were partly balanced by the arrivals of 27,678 French subjects from the home country settled in the recovered provinces.

Before the war there were in the imperial territory 1,428,343 Catholics, 409,274 Protestants, 50,483 Jews. The percentage of illiterates throughout Germany was 17%. In 1914 Alsace-Lorraine contained 1,176,000 tons of goods, 908,000 tons of which went to Germany. In 1919 eight out of ten and a half million tons of exports went to Germany while nearly half of these imports came from Germany. The preponderant part of Germany is naturally explained by the fact that while trade was free with Germany it was impeded with France by the customs wall. It is not possible by a stroke of the pen to change the commercial orientation of a country nor to find at once new markets for its products. Therefore the Treaty of Versailles laid down that for a period of five years nothing should be changed from the customs point of view in the relations between the recovered provinces and Germany.

In Alsace the textile industry is by far the most important, especially in spinning, weaving and printing. France, thanks to the restoration of the province, has nearly all her productive power concentrated in it. The value of the 1920 vintage was 174,000,000 francs. The average tobacco crop is 4,000,000 kilogrammes.

**Mineral Wealth.**—While petroleum and potash are found in Alsace the most important discovery of the moment is the E. of Woerth (Worth) in the Bas-Rhin, where the Pechehollin field is situated. Between 1913 and 1921 about 3,000 borings were made and over 300 pumps were installed in this field. The average output during 1918-19 was 2,250 tons. The small yield, however, affected the whole of the area in 1921, and handed over their exploitation to a private company, mainly formed by local interests.

The return of the department of the Upper Rhine to France deprives German industry of the monopoly of potash. Potash was discovered in large quantities in 1904 in Alsace by the Alsatian

After the Armistice there was a steady drop in output, due to production difficulties of all kinds. This fall was followed by a downward curve being shown by later figures, which are as follows:—

The fresh fall in 1919 was due to strikes and the reduction in working hours. Seventeenth of the coal is consumed by local industry. The Lorraine salt mines produced 28,822 tons in 1919 as compared with 39,901 tons in 1913.

**Public Instruction.—**Strasbourg University was opened by President Poincaré on November 22, 1919. By the end of 1920 the six faculties and the Pharmaceutical School had 1,889 students. The lectures are given in French.

Secondary education is provided by the many lycées created throughout the country, each naturally is the chief language, but German has been allowed to have the place which it is due in view of the special situation of the provinces.

The language question has been more difficult to solve in primary schools. Before 1870 France had neglected the importance of teaching French in the primary schools of Alsace. Since 1920 the teaching has been in French throughout the country. An exception is however made for religious teaching (4 hours a week) which is given in German in those districts where the Alsatian dialect is the mother-tongue of the inhabitants. The religious character of schools has been respected. In view of the bilingual character of the country a large amount of time is given to the study of German in schools, but the population is well educated. Before the war there were only eight illiterates among the contingent of army recruits (97,654).

**Industry.**—After 1880 Alsace-Lorraine had been turned industrially towards Germany. In 1914 Lorraine-Lorraine and Germany were a million 1,176,000 tons of goods, 908,000 tons of which went to Germany. In 1919 eight out of ten and a half million tons of exports went to Germany while nearly half of these imports came from Germany. The preponderant part of Germany is naturally explained by the fact that while trade was free with Germany it was impeded with France by the customs wall. It is not possible by a stroke of the pen to change the commercial orientation of a country nor to find at once new markets for its products. Therefore the Treaty of Versailles laid down that for a period of five years nothing should be changed from the customs point of view in the relations between the recovered provinces and Germany.

In Lorraine the textile industry is by far the most important, especially in spinning, weaving and printing. France, thanks to the restoration of the province, has nearly all her productive power concentrated in it. The value of the 1920 vintage was 174,000,000 francs. The average tobacco crop is 4,000,000 kilogrammes.

In Lorraine iron and steel industries are at the head. There are 68 steelworks, situated with an average capacity of 14,014,137 tons which a steel production of 12,220,000 tons. The production fell from 3,466,000 tons in 1913 to 1,129,000 tons in 1919. The steel output in 1913 was 22,250,000 tons and in 1919 it had fallen to 81,000 tons. This drop is to be attributed entirely to coal and coke shortage. There were 22,000 workmen employed by the industry.

Communications.—The railway system is excellent and has been developed greatly by the Germans, mainly from a point of view. The railways have preserved their autonomy and constitute a special system attached to the Ministry of Public Works. In the 1920 the traffic amounted to 2,533,000,000 tons of goods.
chief French eastern port. It handled 1,324,177 tons of goods during the first ten months of 1920.

Central to the Allied provinces are the richest of France. Deposits in savings banks in 1910 amounted to 462,281,426 francs. The best figure during the German occupation was 289,684,450 marks.

There were no foreign consuls in Strasbourg during the period of Germany's occupation. Since the Armistice Great Britain, the United States, Belgium, Poland, Holland and Spain have established consulates there.

**History.**—There is no need, after the World War, in considering the right of France to Alsace-Lorraine, to refer to the treaty of 1871 and the outbreak that marked historical events in the period before the Treaty of Verdun of 1815. Documents and facts since the end of the Franco-German War of 1870 are sufficiently illuminating. Bismarck, on May 2, 1871—that is to say, eight days before the signature of the Treaty of Frankfort, declared:—"We could do nothing but take these territories with their powerful fortresses within the framework of Germany, so as to make of them a glaci of Germany against France." On Nov. 30, 1875, he again gave expression to this idea of the glaci, saying that the Reichstag:—"We have conquered these ten provinces for the benefit of the empire. It is the course of a good war, and a defensive war, in which we had to save our skins. It was not for Alsace-Lorraine that our warriors shed their blood, but for the German Empire, its unity, and the safety of its numbers. We have annexed these provinces so that Wiessenburg shall not be the jumping-off post of the French in the next attack which they are planning, and which may God delay as long as possible. We have annexed these provinces so as to have a glacis ..."

This brutal glacis-theory is also expressed in a confidential autograph letter, written by the Emperor William I., on Oct. 25, 1870, in which the writer says:—"After having made immense sacrifices for her defence, Germany wants to be certain that the next war shall find her better prepared to beat back the attack which we will have to expect as soon as France has recuperated her strength, or found allies. It is this side consideration alone, and not the desire to aggrandize my country, which is big enough, which forces me to insist upon territorial cessions which have no other aim but to push back the starting-point of the French armies which will attack us in future." German writers and historians have declared that Germany fought against the annexation of her German provinces of Alsace-Lorraine, which desired to return to the Germanic fold. The truth is much more simple, and is to be found in the words of Bismarck and the letter of his sovereign. The people of Alsace-Lorraine were treated as pawns, because the new German Empire wanted a glacis. The inhabitants of the two provinces protested through their elected representatives against the treatment to which they were subjected. On March 1, 1871, the deputies of Alsace and Lorraine raised their voices against separation from France. In the solemn declaration made at the Assembly of Bordeaux they said:—"We have been handed over despite all justice and by odious abuse of force, to foreign domination, and we have one last duty to fulfil. Once again we declare that we consider as null and void a pact which disposes of us without our consent. The vindication of our rights shall forever be open to us in the form and measure dictated by our conscience. Your brothers of Alsace-Lorraine, now separated from the common family, will keep for France, banished from her hearths, filial affection until the day when France again returns to take her place." On Feb. 1, 1874, elections were held in the Reichsland, and all the candidates who protested against the annexation were returned. On Feb. 18, they made a protest from the tribune of the Reichsland, in which they said:—"On behalf of the inhabitants of Alsace-Lorraine we protest against the abuse of strength of which our country is the victim. Although in distant and comparatively savage days the right of conquest may sometimes become an effective right; although to-day it may still be justified when it is a question of ignorant and savage peoples, nothing of the sort can be justified with regard to Alsace-Lorraine. Germany has conquered us at the end of the nineteenth century, a century of light and progress; and the people which she has reduced to slavery is one of those in Europe with a most highly cultivated feeling for right and justice. Our heart is irresistibly drawn towards our French fatherland. In electing us our constituents have above all wished to proclaim their sympathy with France."

France signed the Treaty of Frankfurt, and although she always refused to accept the justice of the annexation of Alsace-Lorraine, she continued to honour her signature. The inhabitants of the two provinces, however, were bound by no signature, and their protest against their lot passed through three phases: active protest, 1871-87; passive protest, 1887-1900; legal protest, 1900-14. France took no official part in these movements, and it may be said that the rights of France to Alsace and Lorraine were kept alive by the inhabitants themselves. Germany crushed the country under a system of dictatorship until May 1903; and it was not until 1911 that Alsace-Lorraine was given a constitution, which, moreover, failed to satisfy any political party. Outwardly the situation was accepted, the inexcusable rights of the country, especially the underground wealth, which had been exploited to the German industry, making a bound forward, had brought prosperity; but the relations between the inhabitants and their conquerors were governed by a purely utilitarian spirit which did not conceal the unbelligible gulf between them.

In 1871 Alsace-Lorraine was considered as a glacis for the defence of Germany, and this same theory again found utterance in a different form on Oct. 9, 1917, when Baron von Kühmann, then Minister for Foreign Affairs, declared that Alsace-Lorraine was the shield of Germany.

The feelings of the inhabitants towards France were abundantly clear at the moment of the Armistice of Nov. 1918, and during the entry of the French troops to the capitals. On Nov. 12, 1918, the Parliament of Alsace-Lorraine, elected by universal suffrage in 1911, transformed itself into a national assembly, and on Dec. 5, 1918, the deputies, meeting at Strasbourg, made the following declaration:—"The deputies of Alsace and Lorraine greet with joy the return of Alsace-Lorraine to France. The National Assembly, faithfully interpreting the constant and unalterable desire of the people of Alsace-Lorraine, already expressed by its representatives at the Assembly of Orleans in 1870 and at the Reichsland, resolved to make the French part of the French, and indefeasible the right of the people of Alsace-Lorraine to be made members of the family of France." The president of the Assembly, the Abbé Delsaur, when the full declaration had been read, exclaimed "Le referendum est fait!" Four days later the President of the Republic, adapting M. Delsaur's historic remark, closed his speech by saying "Le Plébiscite est fait!" A year later, on Nov. 16, 1919, the people of the restored provinces took part as Frenchmen in the general elections. These elections really constituted a plebiscite. All the different political parties had included in their programmes a statement with regard to the return of Alsace-Lorraine to France. The Socialist election declaration said:—"To-day in complete agreement with the whole population of Alsace-Lorraine, the Socialist party firmly and without restrictions supports the return of the country to France. The people of Alsace-Lorraine are, and intend to remain, French." The Radical proclamation contained this phrase: "We are French, France is one and indivisible, we are a part of France, we are flesh of her flesh." The Catholic and Democratic parties, in their joint manifesto, stated: "This electoral demonstration must be a moving echo of the solemn words that your fathers in 1871 addressed to Europe and the world you must solemnly renew the expression of your firm and unshakable desire to be, and to remain, French."
whom he admired above all other artists, he possessed probably the largest private collection ever assembled. Velázquez was well represented, as were Van Dyck, Cuyp, Ruysdael, Vermeer, and many others. These collections he bequeathed to the Metropolitan Museum of Art, New York City. Shortly before his death he secured the incorporation of the Altman Foundation, established for the welfare of the employees of the department store of B. Altman & Co., of which he was the head, thus crowning a career long devoted to unobtrusive philanthropy.

**ALVERSTONE—AMERICAN LITERATURE**

117

Especial (1856-1872), sincerity Englewood, Kentland, librettist, was recalled to France, service as military attaché with the British forces during the S. African War, three years as French military attaché in London, and finally, as a general officer, the command of the expeditionary force in the Moroccan campaign of 1897. On the outbreak of the World War, he was, in accordance with the prepared scheme of operations which assumed Italy as an opponent, placed in charge of the 4th Army of the Alps. The great army which had been mobilized for the “continental war” was to be a mere contingency. It became clear that Italy would remain neutral. D’Amade’s troops were taken to reinforce other fronts and he himself was placed in charge of a group of forces formed in the region of Lille and Douai to resist as best it might the unexpectedly wide sweep of the German invasion. Weak numerically, composed wholly of territorial units of the oldest classes, improvised in point of organization and ill equipped, D’Amade’s “army” was in no condition to attempt a vigorous counter-offensive or even a fixed defense, and after a certain amount of fighting in the Cambrial region it was withdrawn to the canal of the Somme, between Amiens and Albert, on November 11, 1918, and the armistice a day later, bringing the four years of the war to an end. His life, however, was not yet ended.

**AMERICAN LITERATURE** (see 1837).—After the year 1910 the American novel developed mainly in the realistic manner, and in a rather remarkable way, the year 1920 being especially notable for the appearance of novels of distinction. The romantic revival in English and American fiction, which began in the last decade of the 19th century, had exhausted itself before 1910. It was succeeded by what might be called the “life” novel, where the entire history of the hero or heroine is given; even where this rather loose biographical method is not attempted, the realistic novels from 1910 to 1922 were marked by a fidelity to fact and a scrupulous verisimilitude which indicated a promise for the future development of the art. Mark Twain and O. Henry died in 1910; Henry James in 1916; W. D. Howells in 1920. During recent years no one, either in the novel or in the short story, eclipsed the work of these men. But some important new writers appeared and two veterans showed increasing power. Booth Tarkington, born at Indianapolis in 1869, who had a wide reputation after 1899, began in 1914 a series of novels superior to anything in the preceding 15 years of his career. These later novels may be divided into two classes—those dealing with towns and those dealing with youth. In The Turmoil (1915) and in The Magnificent Ambersons (1918) he analyzed and described life in American cities; in Theodora (1914) and in Seventeen (1916) he gave a faithful analysis of the character of the American boy and of the American youth; while in Alice Adams (1921) he portrayed with subtlety a young girl. It should also be mentioned that his sympathetic portraits of negroes were among the best ever produced. Edith Wharton’s Age of Innocence (1920) is her masterpiece; it is a novel dealing with New York society in 1872, valuable for its consummate art and for the accuracy of its historical pictures. The new novelists, unknown before 1910, deal—with the single exception of Anne Douglas Sedgwick, who lived in England—wholly with American life and character.

Dorothy Canfield, born at Lawrence, Kan., in 1879, produced two novels, The Squirrel Cage (1912) and The Bent Twig (1913), the latter describing life in a university in the middle-west, as well as The Brimming Cup in 1921, a remarkable study of a woman’s nature and the grounds of her marital happiness. Zona Gale, born at Portage, Wis., in 1874, took in Miss Lulu Bett (1920) a family and the theme of the unassuming and sincere. The same praise may be given to Sinclair Lewis, born at Sauk Center, Minn., in 1885, for his novel Main Street (1920). Mrs. Mary S. Watts, born in Delaware Co., O., in 1868, wrote a series of realistic novels of American life, of which perhaps the best is the Rise of Jennie Cushing (1914). Henry Sydor Harrison, born at Swannee, Tenn., in 1880, produced one novel of unusual charm in Qued (1911), followed by another almost equally successful, V. V. ’ s Eyes (1913); his prolonged war service interrupted a promising career. Joseph Hergesheimer, born at Philadelphia, Pa., in 1881, wrote a novel the front rank of American notoriety by the extraordinary beauty and distinction of his prose style; he was a master of English composition, as shown in The Three Black Pencils (1917) and Java Head (1919). Another distinguished American writer was Anne Douglas Sedgwick, born at Englewood, N.J., in 1875, who lived in Europe from childhood. Her powers, both of analysis and of style, appear to especial advantage in The Encounter (1914) and The Third Window (1920), while her short story, Autumn Crocuses (1919), is perhaps the best piece of fiction produced by an American under the influence of the French school. The experimental school of fiction had a representative in Theodore Dreiser, born at Terre Haute, Ind., in 1871. His first novel, Sister Carrie (1900), is perhaps his best. The Drama.—From the literary point of view the drama was not important. No play of universal significance has ever been written in America, yet the work of Clyde Fitch (1865-1900) was clever and original; his best plays illustrated very well the metropolitan society at the beginning of the 20th century. Augustus Thomas, born at St. Louis, Mo., in 1859, wrote many plays of western life, but his masterpiece is The Witching Hour (1908). Booth Tarkington produced a successful and literate comedy, Clbourne (1916). George M. Cohan, born at Providence, R.I., in 1878, had an astonishingly successful career as librettist, producer and actor, which was, on the whole, the result of a steady development; his play The Tamer (1906) was not only original, but had distinct literary merit. Louis K. Anspercher, born at Cincinnati, O., in 1878, produced an excellent drama, both from the literary and theatrical point of view, The Unnourished Woman (1915). Eugene Walter, born at Cleveland, O., in 1874, showed talent for melodrama, and in one play, The Easiest Way (1913), for something higher. The death of Mark Twain made George Ade, born at Kentland, Ind., in 1866, an assured literary success as librettist, producer and actor, which was, on the whole, the result of a steady development; his plays, The College Widow (1904) and Father and the Boys (1907), exhibited a talent that the author did not choose to develop. He might have become the leading American playwright.

Poetry.—The World War had a powerful effect on the production of poetry, but a revival had set in about the year 1910, which in 1921 had shown no sign of abatement. The general interest in poetry and the immense number of young poets were notable phenomena; yet it is true that no great outstanding figure appeared—no one who for a moment could possibly rank with Poe, Emerson or Whitman. A leader in modern verse was Edwin Arlington Robinson, born at Head Tide, Me., in 1869, whose first volume appeared in 1866, but whose best work was certainly after 1910. In The Man Against the Sky (1916) and...
AMERY, L. C. M. S.-AMIR 'ALI, S.

The Three Taverns (1920) he combined bold, serious thinking with dignity and grace in expression. A poet who by example and precept stimulated both the love and production of poetry over the country was Vachel Lindsay, born at Springfield, Ill., in 1879. He was the nearest modern approach to the mediæval minstrel. He tramped many hundreds of miles, paying for lodging and meals by chanting his own verses, many of which were written for oral effect. His four volumes of poetry, General William Booth Enters into Heaven (1913), The Congo (1914), The Chinese Nightingale (1917) and The Golden Whales of California (1920), contain works of melody, colour, and imagination. Robert Frost, born at San Francisco, wrote poetry which was mainly of country life in New England, of which North of Boston (1914) is typical. A quiet sincerity, a sharp observation, a steady but low fire of passion and imagination characterized his work. Edgar Lee Masters, born at Garnett, Kan., in 1869, suddenly achieved fame by Spoon River Anthology (1915). Intellectual vigour and irony are its distinguishing features. There is a poetical epiphany for each of nearly 250 persons, each distinctly portrayed, and usually with penetrating scorn. Anna Hempstead Branch was born at New London, Conn., and was a conservative poet, writing in the traditional way with high seriousness. She had passion and imagination and was at her best in poems of home-life. Amy Lowell, born at Brookline, Mass., in 1874, was remarkable as an experimentalist. Her versatility was extraordinary. She wrote much "new" poetry in free verse and in polyphony prose; but she was equally fine in ballads and narrative poems, written in conventional metres. Perhaps her best book is Sword Blades and Poppy Seed (1914). Louis Untermeyer, born in New York in 1885, wrote many graceful lyrics, translated extensively from Horace and Heine, was an admirable parodist, and compiled an anthology, Modern American Verse (1916), which gave a fair review of the field. Among writers of parodies and composers of light verse after the manner of Calverley should also be mentioned Franklin P. Adams, born at Chicago in 1881. One of the foremost lyrical poets was Sara Teasdale, born at St. Louis, Mo., in 1884. None of her contemporaries surpassed her in the art of pure singing. Although Henry A. Sears, born at Buffalo, N.Y., in 1837, wrote sporadic verses all his life, his best volume is The Two Twilights (1917) where his qualities of meditation and passion found full expression. Brian Hooker, born in New York in 1855, wrote notable sonnets and a powerful commemorative poem of the war, A.D. 1916. William Rose Benét, born at New York in 1886, had imaginative creation, shown particularly in Merchants from Calhoun (1918). His younger brother, Stephen Vincent Benét, born in Pennsylvania in 1888, was an extremely individualistic poet, with remarkable imaginative power, evident in Heavens and Earth (1920). Percy Mackaye, born in New York in 1875, published many poems and plays; his collected verse—which greatly varies in value—appeared in one large volume in 1916. Conrad Aiken, born at Savannah, Ga., in 1889, had the gift of singing speech, but his verse lacked thought. A representative volume is Earth Triumphant (1914). William Alexander Percy, born in Mississippi in 1885, was a lyric poet of high distinction, much influenced by classical studies. Some of his verse will find the extremes of the method represented in the works of Carl Sandburg, born at Galesburg, Ill., in 1878. His Chicago Poems (1916) are interesting for their local colour and aim. America lost two poets in the war, Joyce Kilmer (1886-1918), whose poem, Trees, seems destined to live, and Alan Seeger (1888-1916), whose posthumous volume had the stamp of genius. His lyric, I Have a Rendezvous with Death, was one of the most notable poems directly produced by the war. Many 20th-century poets are represented in the anthology called The New Poetry, edited by Harriet Monroe and Alice Henderson, published in 1917. The yearly anthology of magazine verse, chosen and edited by W. S. Braithwaite, is a fair indication of contemporary production.

In miscellaneous literature from 1910-21, the most important work in history was the continuation of the History of the United States by James Ford Rhodes; a contribution to the story of the development of the West was A Son of the Middle Border (1917) by Hamlin Garland; in scholarship, the continuation of the Variorum Shakespeare by the son of Horace Howard Furness; the most important and valuable biographical work was the Life of Mark Twain (1912) by Albert Bigelow Paine, followed in 1917 by the Letters; in epistolary literature the year 1920 was made memorable by the publication of the Letters of Henry James in the spring and those of William James in the autumn; the two best autobiographies of the period are The Education of Henry Adams (1918) and The Americanization of Edward Bok (1920). The most important contributions to political addresses and state papers of Woodrow Wilson, President during 1913-21. In addition many books appeared dealing with various phases of the World War. Among such may be mentioned James W. Gerard, My Four Years in Germany (1917) and Face to Face with Kaiserism (1918); Bernard Baruch, The Making of the Separation and Economic Sections of the Treaty (1920); Adm. William S. Sims, The Victory at Sea (1920); Brand Whitlock, Belgium: A Personal Narrative (1919); and Robert Lansing, The Peace Negotiations (1921).

AMERY, LEOPOLD CHARLES MAURICE STENNETT (1873- ). British politician, was born at Gorakhpur, North-West Provinces, India, Nov. 22, 1873, and was educated at Harrow and Balliol College, Oxford. He received a scholastic fellowship in 1897, and, after travelling for a year in the Near East, in 1899 joined the staff of The Times. He acted as chief correspondent to that paper during the South African War, and was also editor of The Times History of the War in South Africa. In 1900 he stood as a Unionist and Tariff Reformer for Wolverhampton East, but was defeated, being also unsuccessful in 1906 and 1910. He was, however, elected to Parliament for Sparkbrook, Birmingham, in 1911, retaining the seat at the election of 1912. From 1909 to 1916 he served with the army, in France and later at Salonika, but in 1917 became assistant secretary to the War Cabinet, and from 1917 to 1918 was on the personal staff of the Secretary for War. In Jan. 1919 he became Under-Secretary for the Colonies, and during Lord Milner's absence in Egypt in the winter of 1919-20 was acting secretary. In 1921 he was appointed Under-Secretary at the Admiralty.

He has published various works, including The Problem of the Army (1903); Fundamental Fallacies of Free Trade (1906); The Great Question (1909); Unity of Strength (1912).

AMI'IL ALI, SEYYID (1847— ). An Indian jurist and Moslem leader, was born April 6, 1847, of an Arab family tracing descent from the Prophet, which migrated from Persia and settled at Mohan in Oudh in the middle of the 18th century. At Hugli College, Calcutta, he graduated in 1867, proceeding to his M.A. degree a year later. Receiving a State scholarship, he came to London and was called to the bar of the Inner Temple in 1873. He had already published A Critical Examination of the Life and Teachings of Mahomed, the first of a series of books of Islamic modernist interpretation and apologias which have given him a recognized place in English literature, viz., The Spirit of Islam (1853), Short History of the Saracens (1869; third ed. 1921) and Elements of Islam (1866). For some years a lecturer on Mohammedan law at the Presidency College, Calcutta, and afterwards president of the Faculty of Law at the university there, his textbooks on Mohammedan law and other legal works are marked by careful scholarship and characteristic lucidity. He was for some time chief presidency magistrate of Calcutta, but for the most part was engaged in practice, literature and non-official public affairs as a member of the Bengal Legislative and later of the Viceroy's Legislative until 1899, when he was appointed a judge of the Bengal High Court, being the first Mohammedan to reach the bench in India. Retiring in 1904 and settling in England, he was the first Indian to be sworn (Nov. 1908) of the Privy Council and to serve (unsalaried, but later with a small indemnity, for expenses) on the Judicial Committee, where he gave the greatest assistance to his English colleagues in elucidating the intricacies of Indian law and custom. But his chief ambition in life was the advancement of the Indian Moslems, both morally
AMMUNITION

119

and materially, along practical and constitutional lines. While cooperating with Sir Seyyid Ahmad Khan (see 24.277) in overthrowing communal apathy and obscurantism as regards Western education, he deprecated his advocacy of detachment from political activity. His establishment in 1877 of the Central National Mohammedan Association, with branches throughout India, the memorial to the Government of India he promoted in 1883, and the consequent resolution of the Governor-General (Lord Dufferin) in Council in March 1885, recognizing the strength of the Moslem claims, constituted a turning-point in the history of the community, and paved the way for its fuller political organization and the reservation of Moslem seats in the legislatures under the Morley-Minto and subsequent reforms. His sustained and anxious interest in the maintenance of Moslem virility and influence throughout the world was shown by vigorous and cogent contributions to newspapers and reviews.

AMMUNITION (see 1.864-73).—The period of the World War witnessed important developments in the design of ammunition. Although the main effort was directed towards quantity production on a scale that no one had foreseen, and therefore to the simplification of manufacture, yet on the other hand fresh designs were constantly called for to meet changing tactical conditions. Air-fighting produced the need for "tracer" and incendiary bullets of rifle calibre and the attack of localities from the air developed the air bomb; with the free employment of thin armour-plate, armour-piercing bullets, radically different from the armour-piercing shell of artillery, became necessary; instantaneous fuzes designed to explode the shell just above ground gave rise to general use for wire cutting; designs of grenades and trench-mortar bombs were brought out in profusion; and chemical warfare produced a varied ammunition which in principle was quite unlike ammunition of the customary kind.

Moreover, the needs of quantity production and in many cases the shortage of raw materials hitherto supposed to be essential to the production of projectiles and their cartridges, themselves led to novelties of design, and lastly in the attempt to increase the efficiency of older weapons brought out of the arsenals to tide over the shortage of artillery strength, the form of projectiles was revolutionized.

The subject of munitions of war collectively—the organization of the munition effort in the principal countries, with its political, social and industrial ramifications, is discussed in the article MUNITIONS. The present article deals with the technical characteristics of Projectiles for Ordnance (considered from the point of view of [a] design and purpose, [b] ballistic form and [c] manufacture); Cartridges (including ignition devices) and Fuzes for Ordnance; and Ammunition for small arms and machine guns.

DESIGN OF ARTILLERY PROJECTILES

The normal modern shell, whether "monobloc" or made in parts and assembled, has the general form of a cylindrical steel body, hollow to receive the filling, with the base flat and the head pointed. Formerly the head was usually shaped with an ogive struck with radii equal to two calibres, or diameters of the body, from centres on a line through the shoulders of the shell. The shape of the ogive was formerly not considered in relation to the contour of the shell; but when higher velocities were introduced, more attention was given to consideration of the contour of the ogive, as an element of the head shape, to obviating of yaw and deviations from parallelism by means of experiments and empirical results derived therefrom.

In further connexion with high velocity, long range and accuracy, the shape of the head was made more pointed, being struck with radii of several calibres, though the shape did not remain truly ogival as the centres were not on the line through the shoulders of the shell. Greater range and accuracy are aimed at by making the outer contour of the rear part of the shell tapered or streamlined (in America the term "boat-tailed" is used), and this again requires the head to be still more pointed, in order to compensate for loss of range due to lessen ed stability, since any stream-line, however small, necessitates the driving band being placed further from the base than would be the case with a cylindrical body, and the supporting surface of the shell is diminished.

Besides the true stream-lined shell, that is one with the body itself formed with a fine point and taper base, there is another class known as "false cap" shell which was first brought into use on a larger scale in the German artillery, and in which a body of normal form, or even not of projectile form at all is fitted with a long thin steel hood called a "false ogive" or false cap, or ballistic cap. This makes the shell in effect a 10-15 c.r.h. shell with its centre of gravity well towards the rear. During the World War this device, fitted to shells of older models, gave important increases of ranging power in all natures of forms in which it was applied, though the joint was not always strong enough or accurate enough to ensure the true centring of the projectile. The false cap is also found associated with the taper base in some cases.

Apart from ballistie efficiency, the design of a shell is largely determined by the stresses to which the projectile will be subjected on firing. The base must be of a strength sufficient to withstand the pressure of the propellant gases, and the walls of the head must be strong enough to avoid fracture or distortion under the firing and rotating stresses.

The general trend of evolution during the war may be illustrated by comparing the characteristics of German naval shell designed before with those designed during the war. The former had thick walls and fairly small bursting charges, the head being struck with radii of less than a calibre and the total length being from 2 to 3 calibres. The latter on the contrary were made with thinner walls to contain a powerful bursting charge; the shape of the rear portion made stream-lined. The head was tapered to a point and usually struck with radii of 10 calibres; sometimes the head was formed by a false cap which in later cases was welded to an adapter ring screwed into the shell proper. The total length was 4 to 5 calibres.

Figure 1. (which is purely diagrammatical) illustrates the general significance and relations of parts as measured in calibres.

The diameter of the body of a shell is slightly less than that of the lands of the rifled portion of the gun-barrel, this provides a clearance or "windage" that ensures the free passage of the shell down the gun-barrel. Pressed into a groove near the base of the shell is a band termed the rotating or driving band; it is larger in diameter than the rifled portion of the gun-barrel so that, on firing, as the projectile moves, this band taking the rolling gives the necessary spin to the shell to keep it point foremost in flight. In several instances in the German and Austrian services, two or even three driving bands have been put on to a single shell, the better to steady the shell during its passage through the bore of a gun.

As a general rule the position of the band should be as near the base of the projectile as possible, it being found that the more rearward position of the band gives the most accurate shooting. On the other hand, a minimum distance of the band from the base is fixed by the minimum amount of material necessary for its support, for thereby naturally a great deal of the power of the shell when the band is forced into the grooves of the rifling and along their spiral, tending to tear off the base of the shell. Further, with stream-lined projectiles the band necessarily has to be placed far enough forward to clear the tapered base; and in Ordnance, where the projectile is carried fixed in the brass case, the band must be

1 This is only possible of course if the twist of the rifling remains uniform; with "increasing" twist only a single driving band can be used. Fig. 10 shows three different German shells with two driving bands.
sufficiently forward to allow the projectile to be firmly secured in the case. The band must be rigidly secured to the projectile so that it will not become detached or turn independently of the shell.

The material employed for driving bands would be soft enough for the band to be readily engraved by the rifling, even when using reduced propellant charges. Such material is of course easily dented, and as damaged driving bands lead to inaccurate shooting and increased erosion of the gun, care is necessary to ensure undamaged driving bands for service. If, on the contrary, the metal be too hard, it will throw an excessive strain on both projectile and rifling. For all these reasons copper ring, cut from a drawn tube and afterwards annealed, has been found to be the best and most suitable material. A cupro-nickel band has been employed with certain high-velocity medium guns using heavy charges. Electrolytic iron and bronze alloys have been experimented with; and during the World War, owing to the scarcity of copper, the Germans tried other metals, such as zinc and white metal alloys; and with two driving bands the upper was made of copper and the lower of zinc. The Germans also tried a novel combination in which the foundation of the band was a strip of ordinary carbon steel on which was a copper covering, the two metals being so adherent as not to be separated.

Copper bands have the drawback of causing so-called "coppering," particularly with high-velocity guns. As the projectile passes along the bore small particles of the copper band are detached and swepted on to portions of the bore of the gun; and if this surplus copper is allowed to accumulate, eventually a copper "choke" results, making that particular portion of the rifling smaller than the remainder, so that if windage is insufficient to accommodate it, either the gun must expand and bulge or the walls of the projectile set in. To get rid of copper choke it was formerly necessary to put the gun out of action and by chemical or electro-chemical processes dissipate the adhering copper. But recently it has been discovered that the copper deposit can be eliminated by using a small quantity of tin-foil between the propellant charge and the projectile; the alloy melts, being reduced to extremely fine particles which are deposited in the bore of the gun; and the tin combines with the copper to form a fusible alloy which is swept away by the next discharge. What are called "decoppering rings" have been tried attached to the shell. The Germans employed strips of alloys such as tin-lead and zinc-aluminium pressed into a groove round the gun. Decoppering charges or rings would be employed after the gun has been warmed by firing; and the gun must be absolutely free from grease or graphite material.

The body (fig. 3) is normally of forged steel with a solid base; a special steel plate is fitted in a recess in the base; and a socket screwed into the head, or the head itself is threaded to take a fuse which completes the point of the shell. If the shell body be of considerable thickness the explosive content is reduced; but on the other hand the shell body is stronger and there is thick metal for man-killing splinters. A thin-walled shell with a maximum explosive content on the other hand is adapted for the attack of material; with an instantaneous fuze it is useful for clearing ground of obstacles such as wire entanglements, and,

A German shell with a steckling band is illustrated in fig. 10 (a).

(T. F. A.)

A useful approximate rule for comparing the weights of shells of different guns (similarity of shape being presumed) is: the half-cube of the calibre in inches is the weight in pounds. By this rule the weight of the shell just mentioned would be 34.5 lb, and that of a similar 59-mm shell would be 103 lb.

(T. F. A.)

with a delay action, for the attack of buildings or dugouts. (A German example is shown in fig. 4.)

![Fig. 4.](image)

In the British service the explosives in general use for high-explosive shell are T.N.T. (tri-nitro-toluene, or trolty), a mixture of ammonium nitrate and T.N.T. known as amatol, and mixed in different proportions, and picric acid (lyddite). These explosives, especially amatol, are, under proper filling conditions, inert and safe substances, as they have to be if they are to sustain the shock of discharge from the gun. To ensure the necessary complete detonation therefore, an "exploder"—in principle a small charge of less inert explosive—is interposed between the fuze and the bursting charge proper.

The British method of inserting the bursting charge is by melting the explosive in a hot-air chamber and pouring it, in liquid form, through a funnel into the shell. Filling through the base seems to be in favour in Germany; and the general method of filling is with one or more blocks of cast, or pressed, explosive enclosed in containers of varnished cardboard, linen or paper; a more uniform density of bursting can thus be obtained. In some German H.E. shell the bursting charge is separated into two portions by a diaphragm which is pierced with holes for communication between the two charges. In every case a cavity is made in the centre of the filling, nearest the fuze, to receive the exploder which, being detonated through the medium of the fuse, in turn detonates the filling of the shell. Sometimes the relay element interposed between fuze and main bursting charge is contained in a "gaine" screwed to the fuse itself; the metal walls of the gaine confine the contents long enough to guarantee a good detonation and so a sufficient shock to the main charge. Between gaine and charge, if there is room, a small exploder is inserted to make contact intimate and the propagation of the shock more certain.

With 80/20 amatol, which in complete detonation gives practically no smoke effect, some smoke-producing mixture is included in the filled shell to assist observation.

The bursting charges for German H.E. shells are principally amatol of a mixture 13 to 7; frequently they are of trolty; and dinitrobenzene and tri-nitro-anisol have been used. Ammonal and "ekrast" have been used in Austria. With the German 17-cm. H.E. shell the explosive is trolty, and in two containers, the exploder cavity being formed in the upper portion in which a brass exploder container is placed; with the 24-cm. H.E. shell two exploders are used.

A typical high-explosive shell is shown in fig. 5; the steel body is stout, giving great strength and thick metal for fragmentation; the amatol filling is in the form of blocks; the centre block is of T.N.T. which when acted on by the fuze and exploder, facilitates detonation and gives smoke to assist observation of fire.

![Fig. 5.](image)

(b) Shrapnel shell is essentially a man-killing projectile; but shrapnel was employed during the World War for wire-cutting

1 With lyddite fillings the exploder system takes the form of a bag of picric powder inserted in the cavity in the filling; the picric powder is readily ignited by a gunpowder-filled fuse and burns rapidly to detonation. With the other high-explosive filling, particularly amatol which is difficult to detonate, the exploder is T.N.T. in crystalline form, inserted in small bags or cartons. Pellet exploders may probably take the place of exploder bags and cartons so as to give still more intimate contact between fuze and exploder. With T.N.T. exploders, as gunpowder-filled fuses are not suitable, a detonating or high-explosive-filled fuse is employed.

2 Ammonal was employed in the British service for trench-mortar bombs and for grenades, but not for artillery shell proper.

(C. F. A.)

and for long-range fire against observation balloons. In order to get as many bullets as possible to be packed into the shell, the walls are made as thin as is consistent with the shell body being able to withstand the firing and rotational stresses which act on it in the gun and during flight. With shrapnel fire, the normal practice is to open the shell in the air so as to release the bullets in a compact mass, their velocity at the moment of release being slightly accelerated by a small opening charge of gunpowder placed in a recess in the base of the shell below the bullets. To ensure the ready release of the bullets it is necessary to have either a separate and lightly attached head (in the heavier shell such as that in fig. 6), or a fuze socket held not too securely (in the lighter types fig. 5a), so that on the ignition of the small gunpowder charge in the shell, the head or the fuze-socket is readily blown clear and does not impede the release of the bullets.

The effect of a shrapnel shell depends on both the weight of the individual bullet and the number of bullets. To obtain high-striking energy—or rather to ensure a great depth of effect (this being defined by the point of burst of the shell and the point at which the released bullet ceases to possess adequate striking power)—the weight of each bullet should be kept as large as possible. On the other hand the larger the bullets the fewer of them a given shell will contain. The best compromise is obtained by making the bullets spherical and of a heavy metal. The bullets for British light field shrapnel run 41 to the lb., and for heavy field shrapnel 33 to the lb.; in special cases much heavier bullets are used.

![Fig. 6.](image)
follows up of the blow at the exact spot acts in so forcible a way that between the limit of elasticity and that of ultimate tenacity, a sensible amount of work must exist. Generally with projectiles for attack of soft armour, hardness is a necessity, and for attack of hard armour, tenacity is a necessity.

Armour-piercing projectiles may be divided into two classes. First come armour-piercing shell (fig. 7), in which the bursting charge is comparatively small, the head and point extremely hard, and the body softer to give greater tenacity. The success of the old Palliser projectiles depended upon the metal used, the mode of casting, and the form of the projectile and distribution of the metal. With regard to these points specially selected iron was used: the projectiles were cast head down (to ensure density and soundness) in an iron chill with the result that the molten metal rapidly solidified and the qualities given to the head by white iron were intense hardness and crushing strength, but considerable brittleness; the form of the head was a fairly long elongated point, and the object in manufacture was to get the metal as far forward as possible so as to impress its momentum on the armour without acting through the medium of the walls of the shell, though the latter were necessarily thick; this method of manufacture obviously diminished the interior capacity and consequently the bursting charge of the shell.

As processes for hardening armour came to be introduced and used, the material for armour-piercing shell was necessarily changed to steel.

Owing to the liability to split spontaneously, due to the strains set up during the hardening process, the shell are stored for several months before being filled, and the bursting charge is contained in a thin aluminium container. The base is removable and a base adapter is fitted, the base being further secured by a copper gas-check plate, steel plate cover, and steel locking ring screwed to the adapter.

Secondly, there are semi-armour-piercing shell (fig. 8), which are practically common shell pointed, designed to effect a certain amount of penetration of light armour, and to contain a large bursting charge. The points are specially hardened, in some cases capped (as in fig. 9) and the bursting charge is held in a metal container.

FIG. 7.

FIG. 8.

FIG. 9.

Hard-faced armour defeats a projectile simply by fracture of the point and such fracture can in a great measure be prevented by a cap which protects the point when it meets the hard skin of the armour, whether the cap be hard and shattered or soft and crushed.

The first introduction of a cap was to allow a projectile to bite armour obliquely; but it is the value of a cap as a support to the point of the shell that has determined its use. Formerly the shapes of caps were designed without any consideration of the contour of
the shell; but in all recent types the cap is made to conform to the contour of the head of the shell. The use of the ogiv radius determines the breadth across the front of the cap, while a certain thickness through the point is required to give satisfactory armour-piercing qualities, and the combined effect of these two dimensions prevents any appreciable reduction in the weight of the cap. The use of a cap introduces a serious disadvantage in that extra weight is put into the head, whereas the heavier part of a shell should be the base. The cap is attached to the head of the shell by notches in the shell or by interrupted ribs. The shear of the cap may require to be built up from two or more pieces; and with heavy shell the cap may be in four pieces.

Fig. 10, showing typical outlines of German shell, taken from the German Heavy-Artillery Ammunition Handbook of 1917, may be of interest as illustrating the tendencies of design discussed above. Here (a) shows the old-fashioned 2 c.r.h. shell, with a front steady-band of copper; (b) shows a false-cap shell without stream-lined base; (c) shows a stream-lined shell proper. (C. F. A.)

PROJECTILE FORM

The general form of the elongated projectile in use for many years prior to the World War is illustrated in fig. 1. The body is cylindrical in form and of uniform diameter except that the "bourrelet" or shoulder swell (3), intended to form a bearing on the lands of the gun, is slightly larger in diameter. Special care is taken in accurately machining this bourrelet, and the average amount by which the diameter of the bourrelet is less than that of the gun is 1/1000 of the calibre.

It was the usual practice for many years to make the head (2) of ogival shape, with the centre of the circular arc in or near the plane of the front end of the body and with a radius of arc varying from 1/2 to 2/3 calibres. When a point fuze was used, as illustrated in fig. 1, its projecting end was sometimes, but not by any means always, made to conform to the shape of the head.

The rotating band (4) was placed at a distance of from 1/5 to 1 calibre from the base, and its width was from 1/4 to 1/2 calibre. In addition to engaging the rifling in the gun and so causing the rotation of the projectile, other functions of the rotating band are to provide a rear bearing for the projectile, to provide a definite seat for the projectile in loading, and to prevent the undue escape of powder gas around the projectile when the gun is fired.

In fig. 1, which illustrates a field projectile, the shell cavity is either cylindrical or larger in diameter toward the front end of the body, and the fuze is at the point.

In naval or coast-defence projectiles, where penetration of armour is desired, the general form is as illustrated in fig. 2.

The great shock to which the projectile is subjected on impact with armour requires thickening of the walls at the forward end and shortening of the cavity. For the same reason the fuze can no longer be placed in the point but must be placed in the base. It is found that armour-piercing properties are improved by adding a soft metal cap (7) to the hard head (2). In order to get a smooth form of head, a hollow "false ogive" (8) was added to the forward end of the cap.

Experiments to Improve Form.—Previously to 1900, bullets for small arms had rounded points and "square" bases. Experiments started about that time in Russia indicated that a marked improvement could be obtained in flatness of trajectory and this improvement opened the way for experiments in all countries to determine forms of artillery projectiles that would give increased ranges (or, for similar ranges, flatter angles of descent and higher terminal velocities). At that period (about 1907) the mounting of high-power ordnance, both field and naval, did not usually permit of elevations in excess of 20 degrees. There was a possibility of increasing ranges by modifying existing mounts or building new ones, but such a proceeding would have been expensive, and, as will be shown, might not in many cases have increased the range as much as the use of an improved projectile with the old elevation.

Early Improvements in Form.—Even before the adoption of sharp-pointed bullets in small arms, Petrovitch, a Russian, had about 1902 brought out a mathematical discussion of the form of surface which would encounter the least resistance in passing through an elastic medium. This paper helped to encourage experiments to improve the form of head. Firings were made in the United States in 1907 from a 6-in. gun with a 106-lb. projectile having a tangent ogive of 7 calibres radius, using a muzzle velocity of approximately 3,200 ft. per second. The outline of this projectile is shown in fig. 3.

The range obtained was 12,800 yd. at an angle of elevation of 7°, as against 7,800 yd. obtained with the same weight of projectile with a 2-calibre radius and fitted with an armour-piercing cap as shown in fig. 2, without the false ogive. The muzzle velocity with the latter projectile was 2,900 ft. per second. This increase in range of 60% led to other experiments. As it was desired, however, to retain the armoured-piercing efficiency of these projectiles, attention was principally given to the design of a form of head and cap which would make the projectile efficient both for armoured penetration and for range.

Firings were made with the same projectile having the point rounded off, as shown in the following table, which gives the corresponding range and coefficient of form:

<table>

</table>

It was supposed by some, at that time, that the air resistance was principally dependent upon the form of junction of head and body; that little additional resistance would arise if the sharp point was rounded off; and that the rounded form of point would add to the efficiency of the projectile in armoured-piercing. The firings indicated a marked effect on range of even a slight rounding of the point. Armoured-piercing projectiles of the form shown in fig. 3 did not seem
to stand up under the impact as well as those of the older form. But by the addition to the older (2 c.r.h.) projectile of a special cap and false ogive, it was found that not only could the excellent ballistic properties of the 7-calibre radius ogive be retained but, on account of the support given by the special cap, the armour-piercing ability of the projectile was increased. Similar experiments with 12-in. projectiles gave the following increases in ranges of the projectiles with 7-calibre ogives over those with 2-calibre ogives and blunt caps. The muzzle velocity was about 2,250 ft. per second.

It is to be noticed that the advantage of the long sharp-pointed head increased with the range.

Similar tests made in France, England and Germany, with heads long as 9-calibre radius ogive, left no doubt that a very substantial increase in range could be obtained by increasing the sharpness of the point of a longer head. As has been pointed out, the importance of this fact was not fully appreciated until the necessity arrived of obtaining extreme ranges from all guns. When full advantage had been taken of increasing muzzle velocities to the limit of the ability of the guns to withstand the necessary pressures, and means, sometimes improvised, had been used to permit the guns to be fired at the elevation corresponding to the maximum range, there remained only improvement in the projectile to further increase the range.

**False Ogives.**—The hollow extension of the head covering the fuze of field projectiles or the armour-piercing cap of armour-piercing projectiles is called a false ogive. Its use was first suggested in America in 1907 by Capt. W. A. Phillips as an extension for the blunt cap of armour-piercing projectiles. Apart from its effect in lengthening and sharpening the head, and thus increasing the range, no ballistic advantage was claimed for it. Its use with an A.P. projectile is shown in fig. 2. As applied to field the false ogive covers the end of the fuze. It is desirable to make the cavity of the shell as large as possible, and so the walls of the shell proper are run forward as far as they can be, and still permit a tap for the fuze of proper size at the front. The head is then completed by screwing the false ogive over the fuze.

**Improvements in Form of Base.**—Experiments to determine the best form of base commenced soon after these remarkable improvements in range by changes in the head were obtained. In experiments made in 1913 with a 6-pr. gun use was made of ogival and tapered bases coming to a point, the total length of base from the start of the taper being 1 calibre or less.

The resulting ranges were generally less than those of the square-based projectile of otherwise similar form and weight, and they were less accurate. Bases of 1-calibre length tapered to a cone of 9° were then tried, but seemed to give no better results than the square. In both these experiments the projectiles had ogival heads of 2-calibre radius. Experiments made in 1915 with 6-in. projectiles of the three forms of base shown in fig. 5, fired with a muzzle velocity of 2,675 ft. per second, at an angle of elevation of 5°, gave the following results:

A small increase in range and greater accuracy is shown by the boat-tailed projectiles.

French experiments made in 1914 demonstrated that the form of base to give the best result with any projectile is dependent upon the form of head used, and vice versa. A similar conclusion had been reached elsewhere.

1 Known also as the ballastic cap or "false cap."

**Influence of Velocity.**—By comparing maximum ranges obtained with various projectiles and velocities with ranges in vacuo, we may obtain a good idea of possible improvements in projectiles.

Fig. 6 shows vacuum range as a function of velocity plotted on a logarithmic scale, together with other lines showing fractional parts of the vacuum range and points showing the maximum ranges of actual guns. The ranges of low-velocity guns fall near the vacuum line, while those of high-velocity guns are much farther away.

**Improvements in Rotating Bands.**—Although the rotating band has performed all its useful functions by the time the projectile has left the gun, it still has to be reckoned with, since it is capable, if improperly designed or loaded, of materially reducing the range and increasing the dispersion. If it has a "lip" (called in Great Britain "gas check") or is thick at the rear, the excess metal will be wiped back on the passage of the projectile through the bore and will form a ragged extension; and when the projectile is free the centrifugal force due to its rotation may be enough to cause this extension to 3

Explanations of fig. 6.—Blocks show velocities in f/s, ordinates ranges in yd., oblique lines the % of theoretical vacuum range obtained in practice. Thus the 10-in. gun, which obtains a range of 26,500 yd. with a m.v. of 2,500 f/s in actual practice, would obtain with the same velocity one of 63,000 in vacuo. 26,500 is 42% of 63,000 and the projectile is therefore spotted between the 40% and the 50% lines.
stand out perpendicularly to the projectile and thus immensely increase the air resistance. Conditions are not improved by the partial breaking-off of this extension or by its incomplete formation in the gun. It is just this irregular form and size of this extension or "fringing" of the rotating band which makes it a possible source of great inaccuracy. Whether fringing actually takes place depends not only on the design of the band but also on the velocity of rotation of the projectile and the thinness and length of the extension formed at the rear of the band. By taking all these points into consideration it is possible to make a design which will give no trouble from fringing. But, apart from the effect of fringing, the rotating band may materially increase the resistance if improperly located. While it is desirable from other considerations to have the rotating band as near to the base of the projectile as possible, it has been found that a better position for range and accuracy, even if a square-based projectile is used, is 1/8 calibre or more from the base. Similarly, if a boat-tailed base is used, the range and accuracy are both reduced if the band is placed just at the beginning of the taper. It should be at least 1/8 calibre forward of this position.

Double and even triple rotating bands close together at the rear are sometimes used, the idea being that this construction will make the band more efficient as a gas check and that fringing is less marked than for a single rotating of the necessary width. Bands near the bourrelet have also been used. A more recent development is the use of a copper bearing band at the bourrelet.

**Optimum Weight of Projectile.**—The question of the weight of projectile to be used with a gun of a given calibre frequently arises. Other considerations besides that of ballistics affect the answer. There is a practicable limit to the pitch of rifling, which has been fixed at about one turn in 15 calibres for low-powered guns, and one turn in 20 calibres for higher-powered guns. With some such limit in pitch of rifling, projectiles cannot be made more than about 5 calibres in total length and retain the necessary factor of stability in flight. There is thus formed a certain upper limit of length and weight. If the projectile is shortened below this limit and the weight reduced, we may assume that, with the use of a suitable quicker powder, the same muzzle energy and consequently a higher muzzle velocity may be obtained; but while the higher muzzle velocity would tend to increase the range, the smaller weight and ballistic coefficient would tend to reduce it. It is evident that for each gun there is some weight of the projectile, called the "optimum" weight, which will give the greatest range, assuming the muzzle-energy constant.

![Fig. 7](image-url)

The weights of similar projectiles vary with the cube of the calibre. Similar projectiles for different calibres, being the same length in calibres, are of equal stability providing the pitch of rifling is identical. There is therefore a practicable limit to the pitch of rifling, which has been found to be about one turn in 15 calibres for low-powered guns, and one turn in 20 calibres for higher-powered guns. With such a limit in pitch of rifling, projectiles cannot be made more than about 5 calibres in total length and retain the necessary factor of stability in flight. There is thus formed a certain upper limit of length and weight. If the projectile is shortened below this limit and the weight reduced, we may assume that, with the use of a suitable quicker powder, the same muzzle energy and consequently a higher muzzle velocity may be obtained; but while the higher muzzle velocity would tend to increase the range, the smaller weight and ballistic coefficient would tend to reduce it. It is evident that for each gun there is some weight of the projectile, called the "optimum" weight, which will give the greatest range, assuming the muzzle-energy constant.

Working out the maximum ranges on the basis of equal muzzle energies. Fig. 7 illustrates the maximum ranges to be expected from 75 mm. guns under the assumption of equal muzzle energies. It is to be noted that the optimum weight increases with the muzzle energy and that the range changes only slowly as we pass from the optimum weight. In the case of large-calibre naval or coast-defence guns a reduction in weight of projectile tends toward optimum, that is, toward increase in range; but the reduced weight and increased velocity of the projectile lead to greater losses of energy in flight, resulting in a smaller striking energy at a given range.

**Manufacture of Shell.**

The material of which a projectile may be made depends largely on the functions required of it. Cast iron is brittle, more or less hard, with low elasticity, practically no ductility, and low tenacity; consequently this material is of no value for a shell which is required to do heavy work at the end of its flight or to promote a good explosive effect, and is somewhat risky when required to stand the shock of discharge from a high-velocity gun. Cast iron, however, is fusible and easily worked, and therefore cheap; it is consequently sometimes used for practice shot with reduced propellant charges.

In the World War it was used for certain chemical shell where the chemical content was liable to attack steel, and—especially by the Germans—as a substitute for steel when the latter could not be had in sufficient quantities; but its use for projectiles is almost entirely confined to such. Wrought iron has a fair tenacity and a good ductility, but it is quite superseded by steel which can be manufactured as easily and cheaply.

**Steel** possesses the characteristics of elasticity, ductility and tenacity, and is sufficiently hard to enable it to withstand the stresses and shocks a modern projectile is required to sustain. Forged steel is fibrous in molecular structure, and is improved by forging, which increases the tensile strength and minimizes the chance of porous metal remaining; the more work put into the forging, the better the quality of the finished material as measured by its tensile strength in the direction of the forging. Cast steel is crystalline in molecular structure and much harder than forged steel and has less ductility and tenacity; it must always be annealed after it has been allowed to cool after casting, in order to dissipate the uneven molecular stresses set up during cooling.

In the case of steel for projectiles the composition includes from 0.35% to 0.7% of carbon and small percentages of nickel, manganese, and silicon. With cast steel, the walls of a shell cannot be so thin as with forged steel because the material is not so good and there always is a risk of blow-holes and porous metal being present.

The chemical composition of the steel for shells is generally as follows:

*The sulphur and phosphorus are deleterious and should be as low as possible.*

*Steel for A.P. shell should have a higher percentage of carbon in order to give harder material.*

† Steel for A.P. shell should have a higher percentage of carbon in order to give harder material.

*The term "forged steel" is still used but the process of forging under a hammer has been discontinued for some time, the hydraulic press being used instead. The hydraulic press is said to work the mass more uniformly than does the hammer, while hollow-forging on a mandrel has the same advantage over solid-forging. Forging should cease at a temperature of about 1,200°F. for if continued below this temperature, the metal tends to become "hammer hard" and internal strains are introduced.*
AMMUNITION

H.E. shell are always made of forged steel; they have cored walls, thicker at the base to give better strength to the shell. The body requires to be as strong as possible so as not to break up too readily and thus lose the value of the pressure set up on detonation; also, unless the best steel is used the body is pulverized instead of breaking up into pieces of a size to form effective missiles. Pointed shell, whose general use is for the attack of armoured plate, requires to be especially thin in the central part. Shells which have been made of cast iron, cast steel, and forged steel; a disadvantage with forged steel is that, with a bursting charge of gunpowder, the shell breaks up into a small number of fragments; the stronger the material, the thinner can the walls be made, and hence the larger the bursting charge. Shrapnel shell are generally made of forged steel, though in some larger natures they have been made of cast iron. The shell is required to have a high yield point and breaking stress, as this is essential in order that the body, which is made as thin as possible to provide a maximum capacity for the bullets and opening charge, may be able to withstand the pressures set up on the shell exploding from the gun, and the projectile, or shrapnel, in the air.

A.P. shell are made of either cast steel or forged steel; the points are made extremely hard, and the bodies softer; great thickness of metal is worked into the head, and the walls are made thicker than in other shell.

The steel for projectiles is made by different methods: (1) Crucible, which is largely used on the continent of Europe, particularly in Germany. With this method there is difficulty in obtaining uniform quality. (2) Bessemer, which does not lend itself to the careful control necessary for production of the steel suitable, though the method is rapid and cheap. (3) Open hearth. The acid process is preferred to the basic as more suited for production of steel of uniform quality, and more economical. As it does not remove the phosphorus, a purer pig-iron must be used.

The manufacture of H.E. shell (other than solid-pointed) is carried out in a hydraulic press. The cast-steel ingot is heated up and punched, care being taken to ensure a central cavity in the forging; for larger shell several punches or drawings, with intermediate heatings, may be necessary to produce the required dimensions. The forging is then oil-hardened by heating up to a specified temperature and quenching in oil. Analytical and mechanical tests are next applied to samples, and if satisfactory, the forgeries are sent to the machine shop for machining and centering. The shell are then heated to a dull red heat for the purpose of "heading" or "bottling" the cover or ogive to the head; this is carried out lower edge forcing the head of the shell into a die by hydraulic pressure, and can be done cold, but cracks are liable to occur at the shoulders on account of the internal stresses. For "bottling" larger shell, it is sometimes necessary to taper the Absolutely previous to carrying out this operation. The head is then bored and screw-threaded to receive the fuze-hole bush, and the exact ogive given in a "radiusing" machine, which is similar to an ordinary lathe, except that the tool-carrier is designed so as to allow the tool to act on the head of the shell at a variable distance. The base is then faced and turned down to the required thickness. There are also other machining operations necessary, such as recessing the base to permit of the detection of any tendency to weakness at the centre, after which examination a steel disc is inserted in the centre of the base and either screwed in or secured by burring some of the metal of the interior of the shell is sand-blasted, coated with copal varnish, and stoved for six hours. This process gives a very smooth internal surface and it prevents premature explosion from friction, in case of any movement of the projectile resulting from the shell previous to carrying out this operation. The groove for the driving band is machined, the sides of the groove being slightly undercut to assist in holding the band in place; the bottom of the groove has three or four waved ribs cut across it to prevent the band from rotating in the groove, and two or three chisel-cuts are made across the ribs to permit of the escape of any air and driving pressure from the gun.

The driving bands themselves are made of discs of copper as free from impurities as possible, the best kind being that which has been electrolytically deposited. The discs are formed into cups and then heated and drawn through a series of dies to form a long tube, five draws being the usual number. The copper tube is then parted into rings, which are given a final annealing. For banding, the shell are placed in a machine which consists in a circular holder, of which the periphery is divided into segments to which hydraulic presses are attached; a copper band is placed over the shell and retained in position by indenting the shell edge into three pieces. Other bands are also in use.

Shell Manufacture in War Emergencies.—In the adaptation of the engineering industry to the manufacture of shell, the capability and the necessity to turn out the required quantity of war material, and work the bodies of the gun and other parts over the fuze, hold inside a steel cover which is bound to the adapter base by a locking ring. In such designs the adapter base flange is prepared accordingly during manufacture (fig. 1).

When caps are fitted, the usual method is to make peripheral notches in the head of the shell before hardening; the cap is soldered to the shell and retained in position by indenting the shell edge into three pieces. Other caps are also in use.

1 As the base is the heaviest part of the shell, it is in this operation that the various shell are brought (as nearly as possible) to uniform weight.

2 These diaphragms can also be made from drop-forgings.

3 In the case of common pointed, the head is not hardened.
in the process of manufacture must be semi-automatic at least and, consequently, the organisation of the shop and the machines have been designed and built with the object in view that the labor employed must be arranged for purely repetition work, for which it can be trained easily and quickly.

Having regard to this, and to the capacity of an ordinary engineering shop, it is essential to allocate only a certain number of stages in any one process to any one workshop, suitably arranging the stages to the power of that shop.

As this cannot be found in an engineering shop can generally be adapted for any of the operations required in the machining of shell. The ordinary engine lathe can be easily converted for the boring and machining of larger shell, and drilling machines and modern turret lathes for the same operations with smaller shell. The main point to be considered is the provision of suitable jigs and gauges to enable every operation to be performed by semi-skilled labour in rapid and economical fashion. But here no special provision need be made for the pressing on of driving bands, however, the machines necessary are not usually to be found in the ordinary engineering shop; and as it is not easy to find substitutes on account of the high pressures, into chemical, a skin Mannure is necessary to apply that pressure, arrangements for these operations have to be made specially. But with a certain few specially arranged shops of such nature, a supply of part-wrought material could be easily put out sufficient to keep fully employed a relatively large number of ordinary engineering shops adapted for the machining operations, (F. M. K.)

CARTRIDGES AND PRIMERS FOR ORDNANCE

Cartridges for ordnance may be divided into two main classes—technically called " breech-loading " and " quick-firing "—and each class subdivided into gun and howitzer cartridges. All guns are nowadays breechloaders, and the main classes mentioned above are termed B.L. or Q.F. in reference to the system of "obturation" (breech-sealing) employed with the gun. With the B.L. obturation is effected by the breech mechanism, while with the Q.F. it is effected by the cartridge case.

The envelope of cartridges for B.L. guns must be of a material which will stand wear and tear when filled, not deteriorate from chemical action, and have the internal cavity so proportioned as to meet effects on the explosive, and be entirely consumed in the gun when the charge is fired, leaving no débris smouldering in the gun after the charge has been fired. Silk cloth made from the refuse silk from the outside of cocoons has been found to be the best material for the purpose.

The propellant explosive, according to the nature of the gun, is either cordite, N.C.T. (nitrocellulose tubular), or ballistite. All smokeless powders are somewhat difficult to ignite in a gun. Therefore, to make ignition certain and to prevent hangfires an igniter of fine grain gunpowder is used with every cartridge. The igniter is enclosed in a hole of shellstock, which is attached to the cartridge in such a position as to intercept the flash from the tube.

Prior to the use of any batch of propellant for cartridges, it is necessary to prove the propellant, as received from manufacture, in order to ascertain whether it conforms to specification requirements. Cartridges, made up according to the intended design of cartridge, is fired in a comparative trial against a like number of similar charges of a batch of propellant known as " current standard. 4 Current standards are compared in a similar manner with a " master standard," the ballistics of which have been ascertained under certain specific conditions. If this comparison shows that the likelihood of propellant is not to be precipitated by rapid fires in pressure given in the gun, the variation from the standard is found for the batch, and any adjustment in the weight of the charge necessary for the intended cartridge can be determined.

B.L. cordite cartridges are built up of bundles of cordite in the form of sticks cut to the required lengths, and the bundles are tightly tied with silk and inserted into silk cloth bags, of which the ends are closed by discs of similar cloth. An igniter is stitched to the cloth bag, and the whole is sewn to both ends of the cartridge. The exterior is laced with silk cloth tape so as to form a stiff cartridge. The charges for heavy guns are made up in separate portions containing half and quarter charges for convenience of handling and to allow of a reduced charge being used. For some of the longer guns outside the cartridge is made cone-shaped, the coned form being produced by building up the charge with the charge in the bag. The bundle is filled about the gun and has a loop at the top for handling.

N.C.T. and ballistite have been used only for cartridges for smaller natures of guns. The method of making-up need not be described here; but it may be pointed out that, not being like cordite, in the form of sticks, they do not make up into such compact charges as do not need to be handled. For howitzers, variable charges are required, and cartridges must be built so that charges can be readily altered. Moreover, since a howitzer is shorter than a gun of the same calibre a lighter charge of propellant is required, to ensure that no pressure be used up before the projectile leaves the barrel. The cartridge is formed of a mushroom-shaped core made up in a bag to which the cartridge case, when the projectile, attached to the shell, is fitted, is separate from the cartridge. The brass case itself effects obturation in the gun, for, when the cartridge is fired, the case expands slightly and tightly fits the chamber of the gun, thus preventing any escape of gas through the breech.

The use of the brass case influences rapidity of fire in that it obviates the necessity for spewing out the gun after each round to dissipate the hot gases, which, if it could be done, and when the gun was cool again, would be done by own means of ignition, so avoiding the separate operation required with B.L. cartridges. The brass case also offers the advantage of greater safety against the risks of catching fire, and double loading of it is an impossibility.

This class of cartridge is especially useful for smaller natures of guns; but with larger natures of guns the rate of fire is nowadays normally affected by the weight of the charge.

On the other hand the expense of the brass case is a serious consideration; and should a case, by reason of a flaw or split, fail to effect obturation, serious damage may be caused to the gun. Further, the brass must have a certain degree of heat-resistance, involving the use of a special grade of heat-resisting brasscase.

The brass case causes a large increase in weight to the cartridge, and so entails increase in means of transport. And as, to save material and expense, fired cases are collected, repaired, and used several times over, considerable labour is involved in the salvage and transport.

The use of Q.F. ammunition has been restricted in the British service principally to smaller natures of guns; but the Germans have employed metallic cartridge cases for the largest natures of guns, probably on account of the difficulty in ensuring trustworthy obturation by any other means practicable with sliding-wedge breech mechanisms, and also because the service owing to their giving greater safety from premature ignition.

The manufacture of the brass case is a lengthy process and requires care to ensure satisfactory results. The case is made from a brass plate, and requires several stages of treatment before it is ready for use. The finished case is given a thin coating of phosphoric acid which is afterwards removed by baking, and thus the case is presented in a condition ready for finishing and test. The case, when finished, is made quite waterproof by burning with nitric acid, and then varnished in order to prevent corrosion.

The case of the cartridge is placed in the mould or die, and the brass case is inserted. The cartridge is then moulded into shape by pressing it down with a pressing machine, the mould being cut to the specified dimensions and to prepare the central hole in the head for reception of the means of ignition. Charges for Q.F. cartridges are made up similarly to those for B.L. cartridges. Wherever possible, the central part of the cartridge is made of brass tube and felt wads are used to fill up the space in the case, and prevent any movement of the charge. The lower end of the charge is splayed out to fit round the hole for the means of ignition, and in cases where this is a cup a small igniter of powder enclosed in a shallow bag is placed next the flash hole of the cap in order to increase its effect.

With fixed ammunition the mouth of the brass case is closed by the projectile, which is covered on the outside, below the driving band, with a cement to give a water-tight joint, and retained in position either by the lip of the case being pressed over a slightly raised rim on the projectile, or by a square, metallic, outer lip of the projectile, being pressed into a groove on the periphery of the projectile. With separate ammunition a cardboard disc and felt pad are inserted above the charge, and then a lid of white metal or paper is fitted in position by small tongues turned down from the lip of the case.

For cartridges for Q.F. howitzers the charge is made up similarly, the charges are made from a cartridge which has been specially adapted, the separate ammunition must always be used, and the cartridge arranged so that the lid of the case may be easily removable. The mouth of the case is closed by a removable cup-shaped cardboard disc, and sometimes, as a more economical method, by an indiarubber cup which fits tightly round the mouth of the case (see fig. 1).

In order to reduce the flash on discharge of a gun anti-flash charges have been used experimentally. A small charge of ammonium nitrate and a second charge of smokeless powder were placed in each cartridge, and the flash was reduced to a small extent. But the result was not a complete success, and the arrangement was not adopted.
AMMUNITION

With Q.F. cartridges the means of ignition are carried in the base of the brass case, and may be either (a) a percussion cap, (b) a percussion or an electric primer, (c) a percussion or an electric tube held in an adapter. The percussion cap is precisely similar in principle to that of a rifle cartridge and needs no description. The primer is used with larger guns and affords easier means of ignition. In both percussion and electric types the body of the primer is made of an alloy resembling brass; externally it is screw-threaded to screw into the recess prepared in the base of the cartridge case, internally it is recessed to form a magazine. The percussion primer is fitted with a percussion cap resting on an anvil pierced with flash holes; the anvil is recessed to hold a copper ball and retained by a screwed plug also pierced with flash holes. The action is the same as with a percussion tube; internal sealing is obtained by the copper ball being driven backwards in the coned recess in the anvil. The electric primer is similar to the vent-sealing electric type in construction and action.

The primer is being superseded by a vent-sealing tube held in an adapter externally of the shape of the primer. The adapter is bored internally to receive the vent-sealing tube, percussion or electric, which is retained in position by a small stud operated by a spring. Attached to the front of the adapter is a metal container filled with a small charge of gunpowder to augment the flash from the tube.

FUZES

A fuze is the device or mechanism that ignites the bursting charge of a shell fired from a gun, howitzer or mortar. Fuze fall into two categories, those which burst or open the projectile in flight (time fuzes), and those which burst it on impact or graze (percussion fuzes). Of the former all, with the exception of the recently introduced clockwork fuzes, rely for their action on the known speed of burning of a readily ignited composition. In the days of muzzle-loading guns the flash of the powder charge ignited this composition, but in the modern breech-loading guns the passage of the burning gases is checked by the driving band of the projectile, and other means have to be employed for its ignition.

The percussion fuzes in nearly all cases rely for their action on a moveable pellet in the interior which—held in position by a shearing wire, centrifugal bolts, the direct pressure of the powder gases (as in some base fuzes) or other means—is released by the shock of discharge and is free to move. The fuze is then described as "armed." The pellet is provided with a disc of detonating composition at the end which is foremost when the shell is in the gun and on graze or impact the pellet flies forward, and the patch of detonating composition impinges on a sharp point or "needle" in the front end of the fuze, the flash igniting a charge of gunpowder or other explosive in the "magazine" and this in turn igniting the bursting or opening charge of the shell.

In the large proportion of time fuzes the same principle, i.e. the moveable pellet and detonating patch, is relied on for the ignition of the ring or rings of composition. A precaution is necessary, however, with regard to these pellets when time fuzes are to move in the interior of the fuze, as it has been found that they, not being exposed to air resistance, have a tendency to move forward as the shell loses velocity, and thus to cause premature bursts in flight. To counteract this tendency weak spiral or "creep" springs are so fitted as to control the forward movement of the pellet. There are other additional devices to secure the proper arming and subsequent action of the fuze which will be described in due course.

All fuzes are screwed into a bush or adapter either in the head of the shell (base fuzes) or, in case of solidly painted shell, into the base (base fuzes). With certain "false-cap" shell the fuze is internal, that is, inside the false caps, but in it effect a nose fuze in that it is placed in the front of the explosive container.

Percussion Fuzes.—Among percussion fuzes the simplest are those known as direct action, and a British example known as Fuze No. 44 is shown in fig. 1. This fuze is provided with a safety shutter—a device which frequently be made double—so that it will not fire for safety in transport is fitted with a cap and with a safety-pia which blocks the moving parts. On loading, the cap and safety-pia

1 In Great Britain the term "tube" is officially used to designate the smaller firing devices of this class which are pushed into position, and "primer" for the larger ones which are solidly screwed into the base of Q.F. cartridge cases. In the United States the term "primer" is unknown to both. (C. F. A.)

2 In some instances during the war period firing was done by means of a cut-down service rifle screwed into the breach of a gun; in this case an ordinary blank rifle cartridge acted as a percussion tube. (C. F. A.)

3 All fuzes before acceptance as service stores are subjected to rough-usage trials to test their powers of resistance to shocks during transport, and it will be understood that the process of "arming" is necessary both to secure this and to prevent premature action in the gun.

4 Most fuzes have been designed to fire unalike in the gun with the piece, and the American fuzes are the same. (C. F. A.)
attached to it are withdrawn and the head of the fuze exposed. In this is a needle supported by a copper disc over a detonator. Under this pivoted shutter, kept in position by a spring, closes a channel leading down to the magazine, which is filled with a detonating composition known as "C.E." On firing, the shock of discharge does not affect the relation of the parts but, after a certain small interval of time, the rotation is so used that the shutter is swung outwards, overcoming its spring and uncovering the fire channel. On impact the needle is crushed down on the detonator, the flash from which, travelling down the now open channel, fires the magazine and explodes the shell.

Fuze No. 134 (fig. 2) exhibits some interesting characteristics. It is a "delay-action" fuze, i.e., it is so arranged as to burst its shell about 0-20 of a second after impact. The pellet of this fuze is provided with three inclined projections. The constriction of this pellet, of which the upper part is bored out for the reception of the detonator and the lower portion serves as a support for the guard-spring, will be better understood from the figure, which also shows the position of this pellet before firing and when "armed" after firing.

The action is as follows: Before firing, "ramps," or inclined surfaces formed on the upper guard bear against the upper portions of the inclined projections on the detonator pellet, and are held there by the creasing-spring, while the base of the lower guard is pressed upwards against the bottom of these projections by the guard-spring. The two guards and the projections being thus locked by the friction of their surfaces, the guards completely mask the detonator. When the shock of discharge the lower guard sets back, uncovering the guard-spring. The "ramps" on it ride down the inclined projections on the pellet, giving the guard a slight movement of rotation. The upper guard, impelled by the creasing-spring is forced to follow the lower, and the detonator is unmasked. The guard-spring then reasserts itself, and its upward pressure jams the guards in the set-back position. On impact the pellet moves forward, overcoming the creasing-spring and carrying the detonator on to the needle. The flash from the detonator ignites some mealed powder in the interior of the pellet which communicates with the delay composition, this in turn, after the momentary delay desired, igniting the magazine.

Fuze No. 18 is a simple fuze, the action of which will be understood from fig. 3. It is protected by a strong cap which is removed at the moment before loading. The fuze is quiescent in all its parts until direct impact takes place, when the steel hammer is crushed in and, breaking the steel shearing wire, carries its needle-point on to the detonator. The explosion of the detonator fires the loose exploding composition (loose C.E.) in the central channel, which in turn fires the magazine of the fuze (C.E. pellet) and the bursting charge of the shell.

A variation of No. 18, known as No. 45, has a pivoted safety shutter which is similar to that of No. 44, except that when it rotates, instead of merely opening communication between the detonator and the magazine, it brings a patch of composition of its own under the detonator to reinforce the downward flash.

In Fuze, Percussion, No. 106, which is of the instantaneous class, the principal feature is that the fuze is unwrapped by the impact of a steel head and the top face of the fuze body, and it is round this collar that the tape is wound. On firing, the weight at the end of the tape is gripped by the set-back of the hammer, which receives additional support from the steel split collar. When acceleration ceases, that is, when the shell leaves the bore-the weight is released, flies off, unwinding, and carrying the tape with it. The segments of the split collar are torn away by the end of the tape, and the hammer is then supported only by a thin shearing wire. On impact (even the slightest) the hammer is driven in, shearing the copper wire and the detonator is fired. The fuze shown in the figure is a variant, No. 106 E, in which, owing to the inherent sensitiveness of fuzes of this class, a safety shutter is introduced. This shutter, like that of No. 45 alluded to above, carries a composition relay.

No. 106 and its variants were the standard instantaneous fuzes of the British artillery in the World War. Introduced in 1916, some 80,000 were made, and at the end of the war they were being turned out at the rate of a million a week, about one-third of those being made of cast iron.

No. 146, also armed by an unwinding tape device, is known as the "All-ways" fuze. It is designed to act and burst its shell at whatever angle the latter may strike the ground. It is used only for trench-mortar bombs. For rifled shell, which travel nose first, such a fuze is not necessary, but for many trench-mortar bombs, which may strike sideways or on their base, a percussion fuze is impracticable unless it possesses this characteristic. Fig. 5 shows the final form of the British "All-ways" fuze developed in the war from a crude German prototype. It is called No. 146 MK. V., or the Spigot fuze, as it is screwed on to a spigot which projects from the bomb.
An example of this class is the British Fuze No. 101 E. It will be seen in fig. 6 that the detonator is contained in the grazed pellet. With this arrangement it is possible for the needle to strike the detonator when the cap is crushed in an impact (although the grazed pellet may not have acted).

The shock of discharge causes the detonent to set back, compressing its spring. Then the detent detonation, researthing itself, jams the point of the detonent under the projecting shoulder, so that it cannot return to its original position blocking the centrifugal bolt. This bolt, actuated by the rotation of the shell, moves onwards, freeing the grazed pellet. The latter is restrained from working forward during flight by a creep-spring. On graz or impact the pellet, overcoming the creep-spring, flies forward, and the detonator is fired by coming in contact with the needle. The flash passes into the "gaine" and this detonates the shell.

In the earliest models of this class the detent alone was relied upon to give safety, but in the fuze illustrated and also in others, as an additional precaution, a shutter is introduced to mask the flash-hole until the shell is clear of the gun. This consists of a block held in the closed position, with its centre of gravity eccentric to the axis of the fuze, by a compressed spring and a detent with a weighted head. While the shell is going forward in the gun, the shutter is held in position by the spring, but on leaving the gun the rotation of the shell overcomes the spring, and the shutter moves outwards, uncovering the flash-hole. At the same time the tail of the detent is released from its recess in the shutter, moves to one side, and prevents the shutter from returning and masking the flash-hole.

The pellet is locked in its rearward position by a bolt projecting into a recess in its body, and is held in this position by the stem of the pressure-plate. This plate is fitted into a socket, and is made accident-proof by a steel protecting plate, perforated so that the gas pressures may act on the pressure plate.

High explosives used as bursting charges, being comparatively inert and safe substances, require a violent detonation actually in contact with them to ensure that they shall detonate and not merely explode. This result is obtained by interposing a certain amount of less inert explosive between the bursting charge and the magazine of the fuze. In some cases this relay or part of it is placed in a steel or bronze container called a "gaine," which is screwed to and forms an integral part of the fuze.

Fuzes of the class described here are always used with a gaine (which is screwed into an adapter and so secured to the base of the fuze), the flash being inadequate in itself to secure detonation of the contents of the shell without being aided by a relay. The usual arrangement of a gaine for use with these fuzes will be seen in fig. 7.

The flash from the fuze ignites the perforated pellet. The flame from this passes through a flash-hole to the detonator, which, when fired, detonates in its turn two pellets of exploding composition (C.E.) or of picric acid, and these finally detonate an "exploder" bag placed choke downwards below the gaine in the cavity of the bursting charge. This train of three detonations detonates the H.E. in the shell. When a delay composition is included it is placed at the mouth of the gaine, above the powder pellets.

**Base Fuze.**—These are for use in shells having solid-pointed heads. That in general use for common-pointed and armoured-piercing heads comes under the category of graze fuzes and is known as Fuze Percussion, Base large, No. 11.

The pellet is locked by a device which primarily releases it when acted on by the pressure of the propellant gases, its final release being accomplished by the rotation of the projectile. Safety shutters prevent the magazine from being fired should the detonator act prematurely.

FIG. 7

| Plug | C.E. Pellets | Detonator | Powder Pellets |

When the pressure plate is driven in on firing, a recess in the stem is brought opposite to the fork of the retaining bolt, so that this is now free to move outwards. The mushroom-headed centrifugal bolt moves outwards on rotation being set up, and forces the end of the retaining bolt into the recess exposed by the movement of the pressure-plate stem. At the same time the tail of the centrifugal bolt—which has been engaged in a recess in the bolt in the fuze, has prevented the rebound of the pellet on shock of discharge—is withdrawn and the pellet is now free, its movement being only controlled by the creep-spring of the needle.

On impact the pellet moves forward and the needle penetrates the detonator. The flash from this passes through a passage in the pellet and centrifugal bolt, along a transverse channel, and ignites a vertical column of compressed powder leading to the magazine. This is a ring of compressed powder in a recess in the upper part of the fuze body, the powder being grooved on the under side so that the flash may pass all round and ignite the whole ring simultaneously. The flame from the magazine passes through holes in the cap to the bursting charge of the shell.

Premature action on this fuze is guarded against in three ways: First, the spindle of the centrifugal bolt masks the passage through the pellet until the shell has gained a suitable speed of rotation; secondly, the coned seating at the base prevents the escape of flash coming over or through the pellet; and thirdly, a ball in a seating at the end of the transverse channel is held in position by a spring-controlled plunger that moves outwards, the ball following it when sufficient rotary movement has been set up. To prevent a "blind" being caused on impact by the rebound of the pellet, there is a spring-loaded bolt in the side of the fuze so arranged as to enter a recess in the body of the fuze when the projectile has gone forward a certain distance; this permits of further forward movement but no backward movement or rebound due to the creeping spring.

One of the earliest and simplest of the base fuzes is the Base Hochkiss Fuze (fig. 9) used mainly for small Q.F. guns.

FIG. 8

On the shock of discharge, the pellet sets back over the needle holder, thus allowing the steel needle to project beyond it. The alloy at the bottom of the pellet cushions against the bottom of the fuze, and a small portion of it dovetails into the undercut recess, round the base of the needle-holder. This forms a weak connexion between the pellet and fuze body, and assists the spring in preventing rebound action. On graz or impact, the pellet and needle set forward, the needle pierces the detonator, and the flash passes through to the bursting charge of the shell.

**Time and Percussion Fuze.**—As their names imply, are intended to burst their shells either in the air in front of the target or on impact. Setting aside for the moment the newly developed clockwork fuzes, the T. and P. Fuzes used in Great Britain depend for time of burning on rings of compressed composition which are ignited at the moment of discharge, and of which the flame is conducted by suitable passages to the magazine. The opening charge of the shrapnel is thus fired at a moment predetermined by the setting given to the time rings above.
mentioned, one of which is movable, the other fixed to the body. The rings are pressed together by the cap of the fuze, which is screwed down tightly enough to prevent the movable ring from being shiftedotherwise than by a spanner called a "fuze key," so as to ensure regular adjustment of the ring and to prevent it from slipping after being set. Many factors govern the rate of burning of the time rings. Primarily there is the pressure prevailing at the burning surface; this again depends on the pressure produced by the burning composition at the escape outlets, and this again depends largely on the speed of revolution and of translation, the position of the outlets with regard to the body of the fuze, the shape of the fuze, the height to which the shell is fired, the barometric pressure, and the nature of the gun from which the shell is fired.

Time and percussion fuzes are used normally with shrapnel, but rarely with H.E. shell.

![Diagram of percussion fuze](image)

**FIG. 10.**

In the Time and Percussion Fuze No. 80 the upper time ring is fixed to the body by pegs, but the lower ring can be rotated for setting (fig. 10). Immediately below the cap is the mechanism for igniting the composition. This consists of a lighting pellet fitted with a detonator and supported by a stirrup spring which keeps it away from the shell below it.

On shock of discharge the pellet sets back, straightening out the arms of the stirrup spring, and the detonator comes in contact with, and is fired by, the needle. The flash from the detonator passes through a slanting channel and ignites the composition in the upper ring. The flame then travels in the direction in which the shell is rotating until, after an interval of time determined by the setting, it reaches a passage communicating with the lower time ring. Here there is a compressed powder pellet to ensure more certain ignition. The composition in this second ring, being thus ignited, burns in the reverse direction until, at the time determined by the setting, it reaches the compressed powder pellets in a passage leading to the magazine, the flash from which, passing down a tube in the shell, fires the opening charge.

The percussion pellet is held away from the lower point of the needle by a ferrule supported by a stirrup spring, a creep-spring preventing any forward movement during flight. On graze or impact the percussion pellet flies forward, and the detonator, impinging on the point of the needle, fires, and its flash passing through the pellet fires the magazine.

![Diagram of percussion fuze](image)

**FIG. 11.**

In general arrangement Time and Percussion Fuze No. 85 is remarkably similar to Fuze No. 80. There are, however, some important differences (fig. 11). The lighting pellet is supported by a ring sprung into a groove in the pellet and resting on a recess in the stem of the body. On the shock of discharge the pellet escapes from the ring and sets back on to the needle which fires it, the flash igniting the time ring as in Fuze 80. Another interesting characteristic of this fuze is that the gas, instead of escaping directly through holes in the rings, pass into a series of channels before finally escaping through a circumferential groove in the cap. With this modification the rate of burning of the time ring is less affected by variations in barometric pressure and the other disturbing factors above mentioned. The main difference between these two fuzes is, however, in the percussion arrangement. This is of a pivoted needle with bolts, or a detonator supported in the upper part of the recess. The block, which is pivoted, is kept in position by central guilt bolts. These in due course free the block, which swings round its shaft, bringing the needle opposite the detonator. Spring plungers prevent the pellet from creeping forward in flight. On graze or impact it flies forward, overcoming the spring plungers, and fires the detonator. The flash from this passes down the passage in the body (dotted lines) and fires the magazine.

In T. and F. No. 83, a variant designed specially for medium guns and howitzers, a special safety device is provided in the shape of a ball, which is trapped between the ferrule and the detonator pellet and the trigger until the ferrule sets back, where the ball acts as a temporary safety between pellet and striker. When sufficient rotation has been set up, the ball flies up into a side channel, and the pellet is now only held back by a creep-spring which on impact is overcome.

Time fuzes without percussion elements are now of no special interest except in connexion with anti-aircraft fire. It is essential to render all shell fired at aircraft that might fail to burst in the air as harmless as possible on impact with the ground, owing to the danger to friendly troops and the populations of towns and villages, and buildings. Another use of time fuzes without percussion mechanism is in medium-mortar shells which do not pass far. Here a less certain ignition is required, and a few other special cases the ordinary stirrup spring is too stiff to arm, and a weaker spring is fitted with, as its corollary, a safety-pin for securing in transport. All such time fuzes are simply T. and F. Fuzes of the various service patterns converted by the removal of the P. mechanism.

In general the time fuzes designed before and used during the War were constructed to work for 22 seconds' time of flight. In fuzes for certain longer-ranging ordnance, however (e.g. No. 83), 30 and 45 seconds' run was allowed for, and the latest representative of this class, No. 89, which has three time rings instead of two, runs for 60 seconds. Amongst all these No. 89 was by far the most generally used, about 70,000,000 of this type having been manufactured during the war, as well as 18,000,000 of the American No. 85 and 8,000,000 of Nos. 83, 84 and 80. As an instance of how the industry of the country adapted itself to war needs, it is worth mention that the average pre-war output of No. 80 was 35,000 a year, and the output of one firm alone in 1918 250,000 a week.

Last, and for the future most important in the time-fuze category, comes the mechanical or clockwork fuze. This almost eliminates the variations of burst due to atmospheric conditions and to the quality and freshness of the composition used. It had long been sought for by inventors, but until 1916 no type had been produced that gave satisfactory results in practice owing to the great difficulties in designing a mechanism that would run under the conditions of shock and rotation that a fuze must cope with.

In 1916, however, the Germans brought into use a clockwork fuze, ("Dopp. Z. 16") which proved very successful and has been copied, with little variation, by the British authorities, its British designation being Fuze, Time, Mechanical, No. 200. The German clockwork arrangement in addition to the clockwork; this is omitted in the British model, which is a time fuze only.

---

1 This fuze, worked out by J. D. Cushing, was the American army fuze before the World War, and was used in large quantities for British field guns to supplement the available stocks of British fuzes.
which would be rendered useless by the effect of rotation and shock of discharge, and as the length of the straight spring is adjustable, the movement of the piece of the balance, and therefore that of the escapement wheel and the clock train, are controlled and regulated. A horizontal hand, the position of which depends on the setting of the fuze, has on its under surface a notch into which fits the upturned end of the lever at the top of the striker. When the clock train is started the hand moves round with it, but is prevented from rising and releasing the lever by a ring attached to the conical housing of the fuze. This ring is provided with two slots into which the hand can fit; thus when the clock is working the rotation brings the hand into coincidence with the slots, and when forced up by the action of a small spring, it releases the upturned end of the lever. The striker previous to striking has been held in the safe position by a collar on it which rests on a shoulder of the centrifugal bolt, but when this bolt is moved away by the rotation of the shell, the outer part of this shoulder still rests on a steel pin. When the upturned end of the lever is freed from the notch in the lower side of the fuze, as previously described, it flies out and rotates the striker so that the collar clears the steel pin and allows the striker to fall and fire the detonator.

The setting of the fuze and the hand is accomplished by turning the housing with a suitable key, this housing being free to move before firing. On discharge it is very ingeniously clamped to the body of the fuze by means of steel pins in a ring in its under surface. This ring brings a machined bolt, which does not appear in any of the clock case, a groove being turned on its under side to thin the metal, and thus to allow of easy penetration.

The clock train, wound up like a watch, is started at the moment of fuze being set by the setting back of a screw.

The British fuzes described above illustrate sufficiently the general principles on which fuzes are designed to serve the various requirements in war and on various dangers. There are, however, many interesting devices and expedients included in the design of French, German and other fuzes which are not usually employed in Great Britain, and the fuzes described below have been selected as examples of devices and expedients. Some of these have been copied by British designers.

German Fuzes in general have some marked peculiarities. In the first place, especially in pre-war designs, there is a tendency to excessive complication, due to the desire to make one fuze answer for several functions. Ignoring the case of fuzes for universal shell, in which the complication resides rather in the shell itself than in the fuze, we find fuzes designed for time, impact and delay, or impact, delay and long delay, each system having its own equipment of safety devices as well as suitable setting arrangements. In some cases the channels bored into the fuze body with their cross-connecting channels and sealing devices are so numerous that the interior resembles a veritable rabbit warren. One example only of these complicated fuzes will be described here.

On the other hand, some of the devices employed are elegant in their simplicity, notably the interlocking shutter-leaves described in two of the examples below. Other points of special interest found in German fuzes are—in time fuzes the provision of devices to lock the movable time ring by set-back; and in percussion fuzes, and the design and use of the various fuze elements of T. and P. Fuzes the use of pressed powder pellets or columns as a safety device to seal the working parts until the shell is clear of the gun.

The Instantaneous Fuzes, known in Germany as "sensitive" (empfindlich), are quite unlike the British No. 106. Although it appears that the unwrapping device of No. 106 and spigot fuzes originated in a German breech-mortar fuze, it does not appear in any of the instantaneous fuzes used with German guns and howitzers proper, all of which are characterized by a projecting striker rod. This striker rod (very long in the case of shell fitted with false cap) is only inserted at the last moment in the socket chamber for it is the clock mechanism which sets off the sensitive fuzes and are all relatively simple and only instantaneous effect is attempted.

The Instantaneous Howitzer Fuze 16 C. (E.H.Z. 16 C., fig. 13) is fitted with a projecting striker rod so that the fuze comes in contact with the ground, etc., a moment before the shoulders of the shell do so, thus detonating the shell before it has time to bury itself. The removable rod fits into a rod which is supported by a creep-spring at its lower end and held in position up to the moment of firing by two centrifugal spring bolts. Below the point of the needle is a small detonator in a holder also kept in position by two centrifugal spring bolts. Below this is the main detonator, to which the flash from the smaller one is communicated through a suitable channel. This main detonator communicates with the gaine by a fire-hole, but is screened from it by a centrifugal brass shutter, in which—out of line with the detonator-gaine fire-hole—is a charge of explosive.

On rotation being imparted to the projectile the striker needle is freed, as is also the detonator holder below it, and these are then only held apart by the creep-spring. The brass shutter swings outwards, bringing the explosive patch to its position under the main detonator. The fuze is now in all respects sensitive. On graze, the detonator holder flies forward and strikes the needle, which is the body of its cavity, and set-back on discharge does not affect it, bringing against shoulders cut in the body. Alternatively, on impact, the striker rod is pushed in, driving the needle on to the detonator holder. In either case the detonator is fired, and the flash, relayed by the patch in the shutter, passes to the gaine.

In the Instantaneous fuze "Granatindzer 17" (Gr. Z. 17), shown in fig. 14, the body is fitted in its lower portion with a bush carrying five centrifugal segments, a split brass sleeve and ferrule, and a detonator holder, to the top of which a creep-spring is soldered. The upper half of the fuze contains a needle pellet and spring, the upper part of which is shaped to take the striker rod, and has projections that, by a spring, are kept bearing on shoulders formed in the body, as in E.H.Z. 16 C. On the shock of discharge the ferrule sets back, overcoming the support of the brass sleeve, and is locked in its rearward position by lugs on the sleeve which engage in an annular groove in the inner surface of the ferrule. The centrifugal segments are now free to take up rotation about their pivot pins, but as they are interlocked, owing to their shape and position, they can only move one at a time, and thus an appreciable interval elapses before the percussion pellet is free. The extremities of the centrifugal segments (aided by the needle-pellet spring) take up the set-back of the needle pellet on shock of discharge, and the creep-spring keeps the percussion pellet away from the needle during flight. On impact the striker rod is driven in and impels the needle pellet, which, overcoming the resistance of its supporting spring, fires the detonator. Should the striker meet with insufficient resistance to drive it in on impact, the percussion detonator will still fly forward on graze and fire its detonator as it impinges on the needle, the flash passing into the shell through the passage behind it.

This shutter device is also found in an interesting German base fuze (fig. 15), in combination with a detonent of the same class as that of the French No. 101 Fuze, but reversed.

The fuze depends for its action on the inertia of a pellet which remains steady till impact, and then sets forward on to the needle. In travelling, the movable pellet is confined between the shutter and the body of its cavity, and set-back on discharge does not affect it. But as soon as the shutter-leaves rotate out of the way it is perfectly free, not even a creep-spring apparently being fitted. On firing the detonent flattens its stirrup spring, and sets back, and thereupon, under
centrifugal action, the leaves of the shutter, one by one, rotate clear of the head of the inertia pellet. This is of a peculiar design, only found in German fuzes. On two sides the mass of the pellet is continued upwards to form walls or guides, and between these guides is the needle, mounted on a fixed bar. In the upward motion of the pellet, therefore, the detonator carried with it is impelled straight on to the needle. A further peculiarity is to be noticed in the top part of the fuze. This is a delay-action fuze, and in order to damp the violence of the detonator its flash is compelled to follow a long and tortuous channel before it can reach the loose powder which ignites the delay pellet.

German percussion fuzes with optional delay are generally very elaborate; examples, however, may be given of the simple types.

In the 1916 Howitzer Fuze (H.Z. 16) shown in fig. 16 the usual elements—a fixed needle and a movable pellet held by centrifugal bolts, a creep-spring and a shutter containing a relay pellet—appear, and need not be further explained. The peculiarity of the fuze lies in the way in which the fuze is set to act. Both the first and second fuze passes are two channels, both of which it goes. But if the direct channel is blocked by the screw-in valve, the only passage is through the combination of powder, delay composition, and perforated powder in the delay channel; this gives the required delay. In either case a relay detonator below the junction of the alternative channels passes on the ignition to the patch in the shutter and so to the gaine. The blocking or opening of the direct channel is effected, as the drawing shows, by screwing a simple screw valve home or out.

The next example is more complicated, and introduces the device, already alluded to, of powder safeties. It is called the 1904 Shell Fuze without Striker Rod (Gz. Los nach Vorstecker), to distinguish it from the same fuze with a long striker rod used with a false-cap shell (fig. 17).

Above the main detonator is a powder arrangement consisting partly of loose powder and partly of delay powder, with two percussion systems of the needle and brass type above described. A hole from the pellet on one side (section A-A) leads to the central delay, while a similar hole from the other pellet (section B-B) leads to the loose powder under the delay, thus giving delay or direct action as required. The two pellets are held away from the bar-needles by brass plungers with springs pressing on the closed-up tops of the pellet extensions, these plungers being themselves held in position by short columns of pressed powder. From these pieces of pressed powder, columns of powder lead to a platform at the upper part of the fuze body. Here is a movable ring with an annular powder channel on its under side that ignites at will both or only one of the powder columns, in much the same way as the annular element of a time fuze. In the upper part of the fuze, placed centrally, is the ignition device. In the lower part of the fuze and in the gaine, also centrally placed, are the main detonator and the delay fuze. Each of these systems is described presently. Through the body of the fuze run three parallel and distinct systems, each of which is seen in one of the three sections shown in fig. 17. Each of these systems communicates with the ignition device through the head, and with the main detonator and gaine below, in a different way.

Centrally in the head of the fuze is the ignition device, analogous to that of a time fuze and consisting of a detonator pellet controlled by a compressed spiral spring cap, and held away from the needle below it by a split brass sleeve. A flash-hole leads from this pellet to the powder channel in the movable ring, and a second flash-hole to the detonator in the needle. The compressed powder in the columns is consumed and the plungers are freed, the detonator pellets (or, in the case of delay, that in section A-A) can move forward on impact and will be fired by the needles. Meanwhile, in either case the column of powder in section C-C is consumed, the returning rod is free to move, and the brass container moves forward under the action of its spring and fits over the main detonator. On impact, if the ring has been set for delay, one percussion detonator (that in section A-A) fires and ignites the central delay, which then burns through and ignites the loose powder below; and so in sequence are fired the main detonator, the container fitting round it, and the gaine. If the ring be set for non-delay, both percussion detonators (A-A, B-B) fire, but as one (section B-B) is in direct communication with the powder below the delay, the main detonator will be fired without any pause; in other words, the fuze behaves as one constructed for direct discharges correspondingly.

An objection common to all forms of powder safety is the risk of the powder becoming damp in storage or transport; if the safeties fail to ignite, the fuze will fail to act.

No attempt need be made here to describe trench-mortar fuzes; these are in the main impact or delay fuzes of a simple type designed to arm at low velocities. Practically all German trench mortars were rifled, and of the rest the most important types had either a stick or vanes to keep the shell-nose first in descent, so that the difficulty which in England led to the production of the "All-ways" fuze scarcely existed for them. One curious development should, however, be noted—a chemical fuze lasting 1, 2, 24 or 48 hours delay according to the strength of the chemical used. In this, the needle was held off the detonator, against the effort of a spring to decompress itself, by a wire which passed through a container full of corrosive liquid and was secured beyond it to a convenient point on or in the body of the fuze. Kept in tension by the effort of the spring, the wire was gradually eaten through by the corrosive liquid, and finally
parted, wherenpon the spring drove the needle on to the detonator and exploded the fuze.

French Fuzes, in marked contrast to German, are deliberately simple in type and the number of types also is limited. The four patterns described below may be taken therefore as fully representative of French practice.

The typical pre-war percussion fuze is the direct-action fuze shown in fig. 18. The action will be readily understood from the figure. Before firing, a heavy ferrule is supported between a compressed spiral spring and a stirrup spring which surrounds the detonator pellet. On shock of discharge (aided by the decomposition of the spiral spring) the ferrule sets back, straightening the stirrup spring, and fits over both stirrup spring and detonator pellet, being held there by the spiral spring acting as a creel-spring. On impact the pellet and ferrule fly forward together on to the needle, and the detonator is fired. The spiral spring can be adjusted for tension by screwing the closing plug in or out.

A more highly developed design of the same class is Fuze 24/31 P.R. model 1916, distinguished by an ingenious combination of safety pellet and detonator holder which has been copied in the British Fuz No. 134 (fig. 2).

As in other French fuzes, and in British, impact or delay effect is arranged by the design of explosive filling below the main detonator and not by that of elements in the fuze itself.

French instantaneous fuzes are characterized by simplicity and great projection from the nose of the shell, the latter being intended to ensure that the fuze shall act before the shoulders of the shell strike the ground and begin to bury themselves.

A simple representative is shown in fig. 19, which is a cheap and effective trench-mortar fuze. (French trench-mortar projectiles are vaned and so fall nose first.) The striker consists of a head, which in transport is kept off the head of the fuze by a safety ring, and a long striker which is kept centred by a wooden "crayon" in much the same way as the lead is held in an ordinary lead-pencil. Through the head of the striker passes a shearing wire of copper alloy (Cu 67%, Zn 33%). Before firing, the safety ring is removed and only the shearing wire keeps the striker point off the detonator. This resists the shock of discharge (which is relatively slight in a trench mortar) but is sheared on impact. It will be observed that the fuze is not sensitive during flight, as the German fuzes and the British No. 106 are, but relies for its instantaneous effect chiefly on the fact that the striker head takes the ground a moment before the shoulders of the shell do so. A fuze of this class when used with a rifled gun would have centripetal unwrapping tape similar to that of the British 106 Fuze in lieu of the safety ring. The actual detonator arrangements, not shown, may be varied in the usual way by introducing or omitting a delay pellet. The lower end of the fuze is screwed to receive a steel gaine.

As the standard time-shrapnel fuze for the 75-mm. field gun. Unlike the British, German, and other T. and P. Fuzees, it is set, not by means of a movable powder ring, but by punching a hole at the appropriate point in a composition-filled lead tube by means of a fuze-setting machine called a déboucheur.

The time composition is contained in a sealed lead tube fitting into a spiral groove on the upper and slightly tapered portion of the body. Over the body is a cover on which a long spiral scale is engraved, with graduations corresponding to the appropriate points in the composition worn which lies exactly under it. Certain points on the scale are marked with a hole instead of a figure; these subsequently act as a relief for the gases and slag. To set the fuze a hole is punched by the déboucheur through the cover, lead tube, and body, thus making free communication with the interior. The time ignition pellet (which carries the needle in this case) is kept away from the fixed detonator by a coiled spring which it overcomes on shock of discharge. The resulting flash from the detonator ignites a powder pellet, which gives a powerful flame filling the interior of this part of the fuze, and lighting the composition in the lead tube as it passes pellet through the hole punched by the fuze-setter. The composition then burns along the tube until the flame reaches the end of the lead tube, whence it passes by a cross channel to the magazine. (A peculiarity of the French fuze is that the flash from the magazine, instead of passing by a channel of its own to the interior of the shell, ignites the detonator pellet of the percussion system, which acts as a relay.) The percussion system consists essentially of: (a) a ferrule provided externally with a collar and internally with a spring catch device; (b) a detonator holder, hollow to take the detonator and a magazine of fine-grain powder underneath it, and provided externally with a broad flange at the bottom and peripheral ratchet-like notches at the top; and (c) a strong retaining spring and weaker creep-spring. Until the gun is fired the retaining spring, bearing on the collar of the ferrule, keeps this pressed up against the top of the cavity; above the collar the creep-spring is under a slight compression, but this does not affect the security of the fuze. On discharge, the ferrule, overcoming its retaining spring, sets back over the detonator holder, where its internal spring catches engage under one or other of the peripheral ratchet-notches on the holder. The ferrule, compressed spring and detonator holder are now locked together. Held steady during flight by inertia and the creep-spring, on impact they fly forward on to the needle.

In the illustrations, which are diagrammatic, the parts are not to scale, and details (e.g. the centring sleeve for the ignition needle) are omitted so as to show the operation of the fuze more clearly.
The construction and operation of the débouchoir or fuze-setting machine are in general terms as follows (figs. 21 and 22): A hollow rectangular box contains a fuze and shell, fixed in its bottom a fixed socket, threaded internally. A second movable socket (the shell holder) is threaded externally in its lower part so as to be screwed up or down in the fixed socket, and formed internally to take the shoulders of the shell, the fuze projecting downwards through a hole in the bottom of the holder. Fixed about the middle of this movable socket is a gear-wheel, and internally, in its bottom, is a small mortise into which a pinion on the gear engages so that the fuze and shell always occupy a fixed position in the holder. The shell is inserted nose downwards in the holder, secured by the mortise and tenon, and the holder is then, by means of suitable gear in the box operating the gear-wheel, screwed down into the fixed socket, carrying with it the shell and fuze, until the appropriate point in the worm scale of the fuze comes opposite a punching tool in the fixed socket, at which point the tool, operated by an external handle, or, which is more usual, by hand, forces the shell and fuze down. The amount of screwing-in is determined by the number of turns (or fractions of a turn) of the holder gear-wheel, and the internal gear of the box which actuates this gear-wheel is so controlled by a handle on the top of the box that the position of the handle relatively to a dial 1 on the box exactly represents the position of the fuze scale relatively to the punching tool in the fixed socket. (In practice the handle is set and the holder screwed in first, the shell inserted and keyed next, and the actual punching comes last.)

The French service débouchoir is made with two sets of elements side by side having a common dial, corrector scale and setting handle, but separate punching handles. This enables two fuzed shells to be set simultaneously for the same time of burning or successively for different times as desired.

Authorities—No recent book descriptive of fuzes has been published, in the ordinary sense of the word. Information during the war period was circulated only amongst those professionally concerned. The information given above has been collected from various papers and the memoirs of the individual, and chiefly from those sources by the authorities of Woolwich Arsenal, to whom, and to Lt.-Col. G. O. Boose in particular, thanks are due. (C. F. A.)

MACHINE GUN, RIFLE AND PISTOL

Since 1910 rapid strides have been made in the improvement of old and development of new designs of ammunition for machine guns, rifles and pistols, principally due to the World War. The manufacture of small arms ammunition, use by the various nations, may be briefly described by outlining the operations necessary to produce a standard cartridge of any one country. In general, these operations would apply to the manufacture of any cartridge, although slight departures from would be necessary where the designs vary. The metallic components of a cartridge are the case, primer (without chemical composition) and bullet.

The Cartridge Case is made of cartridge brass which, as produced commercially, contains about 67 % copper and 33 % zinc. The brass is furnished in strips, coiled in convenient lengths, which are passed through automatic machines to produce metallic cups, from which the finished cases are evolved by a series of processes generally similar to those described for heavy gun cartridge cases. The Primer, inserted in the head of the cartridge case, consists of a cap made of primer brass into which is inserted a percussion composition of the usual type weighing from 25 to 40 grains, according to the character of the composition. After the assembly of the components, the primer is subjected to a drying operation for a short time to ensure that no moisture remains in the chemical mixture. After inspection it is inserted into the primer hole in the head of the shell fixed in the point between the primer and the cartridge case to provide water-proofing.

The Bullet (unless it be of special type such as armour-piercing) consists of a jacket surrounding a core. This jacket is sometimes a cupro-nicked which, as furnished commercially, contains from 80% to 85% copper and from 15% to 20% nickel. The cupro-nicked is furnished in coils strips from which by automatic machines cups are evolved. These cups are graduated to a series of sizes by divisions after which the nose and profile of the bullet are formed by swedging processes. The core of lead hardened with antimony or tin, may or may not be inserted before the bullet jacket is swedged to form it. Usually, the composite bullet is resized and prepared for union with the cartridge case.

In assembling the complete round the primed cartridge cases are shellacked in the mouth for water-proofing, and are loaded by automatic machines with a propellant powder charge weighing from 40 to 50 grains. The bullets are then inserted into the mouths of the cartridge cases and secured by crimping the top edges of the cases into the cannelures provided (or otherwise, according to the design of the cartridge in question). Small arms ammunition of the various countries is designed and loaded to give muzzle velocities varying from 2,200 to 2,800 ft. per second. These velocities are produced by the velocity of the charge and also by the design of the bullet. The loadings may vary from 200 to 1,000 grains. Cartridge clips for quick loading are used in some form with practically all magazine rifles. The number of cartridges in a clip is usually five, placed one above the other. These clips are usually made with a body of rust-proofed steel or brass containing a flat brass spring.

The loaded ammunition, after being weighed, inspected and clipped, is classified and packed according to its future use. In the United States, ammunition passed as suitable for both rifles and machine guns is packed for issue in bandoleers made of olive-drab cloth, which generally contain six boxes each holding two clips. In most armies such individual packets of ammunition are put up in larger, metal-lined boxes, the number of rounds packed in a box and therefore the weight varies according to the preferences of the military authorities in each.

Packing-boxes are provided with watertight metal liners. In the United States the packing-box when loaded with ammunition weighs approximately 110 lb.; in Great Britain (mark VII, ammunition), 75 to 80 lb.

_Ammunition for Machine Guns_ may be divided into two general classes: first, that for use in machine guns on the ground; and second, that for use in aircraft machine guns. The extensive use of ammunition for machine guns in the World War involved no new processes of manufacture in order to adapt it to the particular weapons. It did, however, require a mechanism of inspection to ensure that the ammunition produced was of a quality suitable to stand the wear and tear of machine-gun action.

Ammunition for general use in machine guns is generally the same as the standard type used in the shoulder rifle, but more rigidly inspected and tested. Several of the belligerents in the World War developed special types of cartridges having heavier bullets than their standard type in machine-gun barrels.

A number of special types of machine-gun ammunition have been developed for use by aircraft, all of which have the same overall length as the service ammunition and may be briefly described as follows:

The _tracer cartridge_, as the name implies, is loaded with a tracer bullet for use with machine guns where, as in aircraft work, it is essential to make the trajectory visible. The bullet differs materially from that of the service cartridge, in that the lead core of the latter is replaced by a conical lead slug in the nose of the tracer bullet jacket; in the rear of which there is inserted a gilding-metal capsule which contains the tracer element. The ingredients used in the composition are dependent upon the type of tracer desired. The red tracer involves the use of strontium salts with the necessary oxidizing agents, while the so-called white tracer gives off a greenish-white flash which involves the use of sodium salts with oxidizing agents. The tracer composition is compressed into the capsule at a pressure to withstand that produced by the expanding cartridge and the length of trace can be regulated by the adjustment of the pressure or by the use of oxidizers. The composition is ignited by the propellant powder flash and burns with a bright light during a minimum of 500 yd. of flight. Tracer cartridges are generally loaded as to give slight ballistics, the service ammunition at 500 yards. As these cartridges are placed in machine-gun belts, interspersed with service, incendiary and other types of special aircraft ammunition, a distinctive marking is provided so that the inspection may be made of each ammunition belt before the airman goes into the air.

Owing to the extensive use of observation balloons and dirigibles in the war, the demand was created for an _incendiary bullet_ which
would ignite gases or other materials with which it might come in contact. Omitting technical detail, this form of bullet is organized to cause the yellow phosphorus in the hole to burn vigorously with a phosphide or aluminium dust in the head. The base is sealed, but a small hole is punched in the side of the bullet and closed with an easily fusible alloy containing a high percentage of bismuth. The heat generated by the burning phosphorus raises the temperature of the bullet sufficiently to cause the alloy to melt, and this in turn causes the yellow phosphorus to become molten. Upon exit from the barrel, the centrifugal force produces a large eddy in the bullet through which the phosphorus burns by the air and other waste products leaving a trail of smoke and fire streaming from the bullet. The bullet can be reloaded or replaced in the barrel by a new one of the same size. The inside of the barrel is protected by uneasy steel or plastic sheets. These cartridges are distinguished by special marks.

The use of various standard-calibre incendiary bullets against observation balloons and dirigibles was supplemented by the development of a larger calibre (11 mm.) tracer incendiary cartridge for use at longer ranges. The bullet is generally turned out of solid brass and are approximately 134 in. long. The tracer incendiary mark is produced by a white or red flame according to the chemical used. This composition is mixed and compressed into the brass cartridge case so as to withstand the pressure of the cartridge when fired. The base of the propellant ignites the composition which burns for at least 1,200 yards. The cartridge case is of the rim type and is loaded with a propellant to give a muzzle velocity of 2,000 to 2,500 ft. per second.

The experiments of the various types of bullets described above have been tried out experimentally with different degrees of success. The inspection of all of these types is very rigid, as all ammunition for aircraft use must be specially selected, in particular because hang-on-firing bullet cartridges can be dangerous in aircraft machine guns synchronized with the propeller.

Many types of armour-piercing bullets were used during the World War I. They were used on anti-aircraft guns, anti-airplane guns, tank guns, etc. The size of each type of bullet, with its steel core, required considerable experimental work and may still be considered as in the development stage. It consists principally of a cupro-nickel jacket, inside which is a hardened steel core that is coated with a lead envelope. The operation may be briefly described as follows:

- Upon striking the armour-plate, the jacket splits and a portion of the lead in the nose of the bullet is trapped between the hardened portion of the jacket and the hardened armour-plate. This soft mass of lead produces a protective coating for the nose of the steel core and thus aids penetration. The bullet is loaded into the same case as the smoke ammunition and is distinguished by special markings. A larger calibre of armour-piercing ammunition was developed by the Germans for the 13-mm. anti-tank rifle (see Rifles). The bullet was of the armour-piercing type and weighed approximately 1.5 lb. in all cases. It is loaded with a propellant charge of about 200 grains. The jacket developed a muzzle velocity of about 2,450 ft. and was very effective against tank armour. Further developments along this line may be expected in the future.

**Ammunition for Rifles.**—Each country has its standard rifle cartridge, which is of the same shape and size and is manufactured in the same manner as the standard round ammunition described above. Some of these cartridges are of the rimmed while others are of the rimless type. The standard calibres vary from .25 in. to .32 in. Various other types have been developed for guard, test, and training purposes, such as the blank, dummy, charged, high-pressure, and gallery-practice cartridges.

**Ammunition for Pistols.**—The ammunition is used in various countries in automatic pistols is very similar, and a description of the manufacture of the United States type may be considered to be representative of all others. This cartridge consists of a drawn brass case with a primer inserted in its head. The bullets, as a rule, have jackets made from drawn glass moulds, and the cores are also moulded. The type of this cartridge and bullet jacket follows; in general, the process outlined for the manufacture of the rifle-cartridge components except that the number of operations is considerably reduced. The bullets are cut from a solid cylinder of lead, which is briefly described and has its jacket tinned and filled with a core of lead hardened with about 2% of antimony. The cartridge cases are all of the rimless type and have a small cannon located on the cartridge case in such a position that it is forced into the barrel when fired. Although the bullet is of the semi-rimless type, a propellant charge of about 200 grains is loaded to give low velocities as compared with rifle ammunition. Calibre .45 cartridge, used by the United States, has a muzzle velocity of 730 ft. per second, with a maximum case length of approximately 3.5 in. While the .45-calibre pistols are the most popular types, there are also .38-calibre and .22-calibre respectively. In addition to the bullet types of the service type, there are blank and high-pressure cartridges for instructional purposes. The ammunition made for automatic pistols is fired from revolvers, pistols, and shotguns in principle similar to that of the heavier .45 pistol. (W. L. C.)

**AMUNDSEN, ROALD (1872–1928).** Norwegian polar explorer, was born at Borge, Smaalenene, Norway, July 16, 1872, the son of a shipowner. He was educated at Christiania and afterwards studied medicine for two years. Later, however, he went to sea, and from 1897 to 1899 served as mate on the "Belgica" with Capt. Adrien de Gerlache's Antarctic expedition. In 1907–1902 he made an expedition to the Arctic regions which resulted in some valuable observations, and from 1903 to 1906 was in command of the Gjøa" on its voyage through the north-west passage between the Arctic and Pacific oceans (see Arctic Regions). The "Gjøa" made the second wintering on the Antarctic continent and the first whaling expedition between 1907 and 1911. Towards the end of 1910 Amundsen started in Nansen's famous ship, the "Fram," for the Antarctic regions. The polar continent was crossed under good conditions, the weather being excellent, while the arrangements for food and transport worked without a hitch. The South Pole was reached between Dec. 14 and 17, 1911, the Norwegian party thus outstripping by about a month the British expedition led by Capt. Scott (see Antarctic Regions). In June 1915 Amundsen left Norway in the "Maud" with the intention of drifting across the Arctic ocean, but at the end of 1919 was forced to abandon the attempt (see Arctic Regions). Capt. Amundsen has published The North-West Passage (1907), and The South Pole (1921), and has received many honours from learned societies.

**ANAESTHETICS (see 1.907).**—In connexion with the progress made in 1910–20, it is somewhat remarkable that the agents for producing general surgical anaesthesia which were the first to be introduced, that is, nitrous oxide gas, ether and chloroform, not only remained in general use, but actually provided in greater part for the requirements of modern surgery. "Regional" anaesthesia, or analgesia as some prefer to call it, had, however, in part superseded "general" anaesthesia. It consists in abolishing sensation in a restricted part of the body without affecting consciousness; it is effected by "blocking" the conduction of sensation through the nerves supplying the area concerned by applying to them a solution of a drug similar in constitution to cocaine, or by injecting this solution into the lower part of the spinal canal and so blocking the sensory fibres in the nerve roots and in the spinal cord itself. Regional anaesthesia has, however, as yet only a limited application, for although adopted as a convenient routine measure in some classes of cases and types of patients, it has been found by experience to have certain limitations, and in the case of spinal anaesthesia certain dangers. Many persons, moreover, prefer the blissful ignorance of a general anaesthesia to full consciousness, and passive submission to a trying ordeal, even when they are deprived of sensation and when the sight of the operation is hidden from them.

General anaesthesia produced by the inhalation of a gas or vapour remains the routine procedure. The use of non-volatile drugs, such as morphia or lozadon, introduced by the mouth or by subcutaneous or intravenous injection, is not readily subject to control; once introduced these substances remain in the body until slowly excreted by the kidneys; the dose can be increased but it cannot be decreased, and herein lies a danger. Inhalation anaesthesia on the other hand is susceptible of the most delicate adjustment to requirements. The pulmonary route is adapted anatomically to meet the vital requirements of the absorption and excretion of the blood gases, oxygen and carbon dioxide, and is hence perfectly adapted for the passage to and from the blood of other gases and vapours. The amount of a vapour absorbed by the blood and the rapidity of its absorption are both proportional to its concentration in the atmosphere inhaled into the lungs so that the task of the anaesthetist is mainly one of adjusting the strength of the vapour according to the result which is desired. There are two general methods of introducing the semi-volatile vapours into the blood; one is to simply inhale the vapour, the other is to exhale it partially and re-inhale it. The latter method is less affected by the temperature of the atmosphere inhaled, and is therefore preferred by all; but it is not possible to absorb from the atmosphere all the vapour exhaled, and so a certain amount of the gas is lost when the operation is prolonged.

In the case of chloroform there is a deviation from the laws of the solution of vapours, but this is negligible at the low concentrations employed for anaesthetic purposes.
Nitrous Oxide.—One of the surgical lessons of the World War was that persons suffering from severe shock and loss of blood from wounds did not progress favourably following operation under chloroform or ether, but that the prospects of recovery were often improved by using the inhalation of an atmosphere containing nitrous oxide gas. The reasons for this cannot be stated precisely, but it may be said in general terms that nitrous oxide is less depressing, and further that owing to its exceedingly rapid excretion the after-effects of its use are considerably less pronounced but it is due to the fact that the absorption of oxygen by the blood is a process of loose chemical combination with the haemoglobin, which is not governed by the laws of the simple solution of gases in liquids, but involving reactions which are not entirely free from the provision of a sufficiently delicate mechanism to regulate and induce the inhalation of the best mixture of the necessary substances which has been generally adopted consists of pressure dials connected with the supply tubes from the cylinders of compressed gases; these are so regulated at which the gases and oxygen passes for a given proportion, that the concentration by the patient is not until the end of some operations; the operation is always supplemented by an admixture of ether vapour; nor is it a method absolutely free from danger. Its advantages in the cases of profound shock required to appear to be understood, but how far it can be adapted for general purposes is not yet undecided.

Ether.—The use of ether as an anaesthetic has received considerable attention in the literature of the "open" method of administration. In order to induce anaesthesia in a muscular person, or to "get him under" in ordinary phraseology, a strong vapour may be required, as strong as 25% to 30% in some cases, but in the case of a delicate subject the inhalation of a sufficient concentration from ether sprinkled on a piece of cloth Filtered over a mask or in order to attain this end a "close" method has been adopted in which ether is inhaled through a rubber bag over a surface of ether. In this way the vapour becomes concentrated in the bag, but at the expense of the oxygen of the contained air, which becomes rapidly used up, so that the inhaler must be removed periodically to allow of an inspiration of pure air in order to obviate total asphyxia. This method is effective, but far from ideal; the patient is generally more or less "blue" from partial asphyxia throughout the administration, there is a profuse secretion of saliva which is collected and disposed of, the respirations are greatly exaggerated from "re-breathing" of the carbon dioxide which accumulates in the bag, and they are often accelerated to a point which is distressing to both patient and operator. The after-effects are generally unpleasant and not infrequently distressing.

In the "open" method the breathing is noiseless, effortless, and regular, and the inhaler is able to perform with comfort. The flow of saliva is considerably less than in the closed method (probably from the absence of asphyxia) and this can be entirely abolished by the substitution of small quantities of water instead of saline. There is no sign of cyanosis, and the patient's face remains a healthy colour throughout; the only restriction of oxygen is by reason of the large surface area of the breathing organs, and the time required is not more than one-third its volume, and as in the later stages of the operation the administration much vapour is required the restriction becomes entirely negligible. The absence of after-effects of ether, such as vomiting and malaise, is considerably less pronounced than following a "close" administration.

The application of the "open" method to ether inhalation has been brought about by an exceedingly simple adaptation. The liquid ether is supplied to a rapid of open-wave fabric, such as "stockinet" or a number of layers of absorbent gauze, stretched over a framework mask of which the margin is roughly adapted to the contours of the face; the mask is lightly applied over the face, a soft pad being interposed between the edges and the skin. With this arrangement the inhaled air is made to pass through the meshes of the fabric, and in doing so every portion of it comes in close contact with the ether, and takes up a given proportion of it, and is distributed over the surface of the face, in the ordinary way of procedure. The induction of anaesthesia by the open method is liable to be somewhat prolonged, an undoubtedly disadvantage, but once full anaesthesia is obtained it is very easy to maintain, and the results are attained in general are more satisfactory than those of any other form of inhalation anaesthesia.

The "intratracheal" method of etherization has in recent years been freely used for special reasons, particularly in obstetric cases. It is conducted by passing a narrow tube through the larynx into the trachea almost to the level of its bifurcation. Through this tube a continuously flow of air and ether vapour is forced into the lungs at a pressure which keeps the lungs moderately distended, but not so much as to abolish the natural respiratory movements. The air returns through the chink of the vocal cords by the side of the tube, and the return blast blows away any solid or fluid particles, blood or pieces of tissue, in the neighbourhood, and prevents their entering the trachea, an accident which may possibly occur in ordinary inhalation methods.

The advantage of intratracheal ether in the case of any very prolonged cases is considerable, and it is likewise a convenient arrangement for operations upon the face, which is left entirely uncovered; and in operations upon the interior of the thorax a proper aeration of the lungs can thus be insured.

The subject of chloroform as an anaesthetic which was generally encountered under chloroform anaesthesia has acted as a deterrent to its more extended employment in spite of its manifest convenience of administration. It is a matter of regret that a committee appointed by the British Medical Association to find a method of preventing these chloroform deaths, by enquiring into the conditions of overdose and devising apparatus for the prevention of chloroform vapoour to essential respiratory danger had a final report of this committee was issued in 1910, but the number of deaths from chloroform has remained practically undiminished since that time. An attempt has further been made to reduce the possibility of overdose by the introduction of special respirator breathing proportions, but this has proved to be futile as a prophylactic against death, for although the number of deaths under pure chloroform has been reduced the other mixtures of chloroform has risen ten times in a period of ten years.

It is now becoming realized that the typical sudden chloroform fatality is not conditioned by an overdose at all. It has long been known that the majority of deaths occur in the very early stages of anaesthesia before the patient is fully narcotized, and further inquiry into reports of fatalities shows that there is generally some evidence of light anaesthesia preceding death, or else that overdose did not precede.

There is a further point brought out by these reports, which was in fact fully appreciated by John Snow in the middle of the last century: whereas in overdose the respiration is paralyzed before the circulatory system in the typical chloroform fatality it is an absolutely sudden failure of the circulation, and the failure of the respiration is a secondary result.

Dr. Robert Haldane, a man of great ability and with strong conviction, advanced the theory that chloroform deaths occurred from underdose, and although his thesis was supported by important experiments, he failed to formulate an acceptable theoretical basis for it. Dr. A.G. Levy, in 1911, reported certain cases of sudden cardiac failure that he had observed in animals obviously in a light stage of chloroform anaesthesia, and he succeeded in reproducing this death by the intravenous injection of small doses of adrenalin in lightly chloroformed animals, but the experiment failed under full chloroform narcosis.

This at once accounted for those cases of syncope and death, a number of which had been recorded, following the administration of chloroform by the "open" method for the purposes of certain nasal operations which were always conducted under light anaesthesia, the form of this sycope being the same as in an ordinary chloroform fatality.

Dr. Haldane's theory was that it was shown that sudden cardiac failure could be induced likewise by various procedures—excitation of the cardiac accelerator nerves either directly or through a reflex mechanism, stimulating the excitation of the arterial glands, introducing the patient to the shock of anaesthesia, to提到的the chloroform during excitement and struggling; the event never occurred during deep narcosis. The underlying condition was the assumption that when the patient is under the influence of the chloroform in the trachea, in which the chloroform is entirely deprived of its power of propelling the blood through the arteries. The seeming paradox of too small a quantity of a drug being dangerous is thus explained; it is the absolute quantity of chloroform that has been fully worked out; a relatively small proportion of chloroform renders the heart "irritable" and liable to assume a sequence of irregular beats which may pass into fibrillation, whereas a larger proportion of chloroform, by reason of its depressing effect, makes
the heart less irritable, and entirely annuls the tendency to fibrillation.

Many years ago J. A. McWilliam expressed the opinion that ventricular fibrillation would be fatal to account for otherwise unexplained sudden deaths met with in various conditions, and this demonstration of its occurrence under chloroform is the first confirmation of his views.

From this theory the prevention of death under chloroform can be compassed by simple precautions, by making the induction of anaesthesia continuous and expeditious and thereafter continuously maintaining a full degree of narcosis. Chloroform should never be employed if the conditions of the operation forbid the observance of these rules, and especially in those special cases in which a light degree of anaesthesia is required. These rules are practically a reversion to the injunctions of Simpson, who introduced chloroform as an anaesthetic and who used it with success. Some, in my experience only one case of death occurred in 10,000 administrations.

Ventricular fibrillation is not always fatal; in more than half the cases the heart spontaneously recovers its normal beat, but this happy result can only occur in the first minute or two following the onset of fibrillation. After that time the only prospect of recovery is through the performance of cardiac massage. This so-called "massage" is a rhythmic manual compression of the heart, producing an artificial circulation; it is combined with an artificial ventilation of the lungs, and so oxygenated blood is supplied to the heart muscle keeping it alive and active, and giving to it a prolonged chance of recovery. In cats this experiment is uniformly successful in bringing about recovery, but in man there have hitherto been only relatively few successes. It appears to be a case that falls far short from an imperfect application of the principles of cardiac massage, and it is believed that with better knowledge the majority of cases of ventricular fibrillation should prove amenable to this form of treatment.

ANCONA, ALESSANDRO (1835-1914), Italian man of letters (see 1.051), died at Florence Nov. 8 1914. In 1904 he had been a senator. Many of the most eminent contemporary philologists and students of literary history in Italy had been his pupils.

ANDERSON, ELIZABETH GARRETT (1836-1917), English medical practitioner (see 1.959), died at Aldburgh, Suff., Dec. 17 1917.

ANDERSON, SIR ROBERT ROWAND (1834-1921), British architect, was born at Forres in 1834, the son of a solicitor. He was educated at Edinburgh and entered the Royal Engineers, where he received his first training as a draughtsman. He subsequently travelled widely in Europe, and later adopted the profession of architect. His first important work was his successful design for the Edinburgh Medical Schools (1873), and this was followed by a succession of important commissions, including the design for the offices of the Royal Scottish railway and the Court, Stuart Lady Bute's house on the island of Bute (1881-4), the Conservative Club, Edinburgh (1883), the dome of Edinburgh University (1886) and the Scottish National Portrait Gallery (1886-8). He also successfully carried out a series of restorations of Scottish cathedrals, including those of Dunblane Cathedral, Paisley Abbey, Culross Abbey and the interior of Dunfermline Abbey. Many of the best-known monuments in Edinburgh are from his designs, and he was among the architects invited to submit designs for the Imperial Institute (1887), the Queen Victoria Memorial (1901), and the new buildings of the British Museum (1904). In 1909 he was selected to superintend the alterations which were being carried out at Balmoral Castle, and in 1902 he was knighted. Sir Rowand Anderson was in 1876 elected an associate of the Royal Scottish Academy, of which he was in 1886 elected an honorary member. He was also member of the Royal Institute of British Architects and in 1916 was awarded the Royal gold medal for the promotion of architecture. He died at Edinburgh June 1 1921.

ANDORRA (see 1.656) had, in 1913, a pop. of 5,210, distributed in 6 communes embracing 44 villages and hamlets. Alt. ranges from 6,562 ft. to 16,717 ft.; alt. of Andorra la Vella, the capital, 7,500 feet. The trans-Pyrenean railway from Ax-les-Thermes (Chemin de Fer du Midi) to Ripoll will pass within 2 or 3 m. of the city, and from here there is an easy access to the Col de Puymorens (alt. about 6,500 ft.) to Bourg-Madame, on the Spanish frontier, is tapped by a branch road (under construction in 1912) entering Andorra at Port d'En-Valín (alt. 7,580 ft.), and running down the Valira valley to the capital.

The revenue of the republic, amounting to about 32,000 pesetas per annum, is derived from the sale of wood from the state forests, the rental of summer pastures, a tax on inns and slaughter-houses, and a levy on the value of crops. In 1913 he received a biennial tribute—France 1,920 francs and the Bishop of Urgel 920 pesetas; the latter also receives annual gifts in kind from each of the six communes. The principal industry is the raising of cattle and sheep and mules. There is a small tobacco factory at the capital and a considerable amount, of poor quality, is exported to Spain. Wax matches are also made. French and Spanish postage stamps, for the north and south respectively, are in use; the telegraphic arrangements are French. Both French and Spanish coins are current. France has established schools in Andorra, and French influence is in the ascendant.

ANDRASSY, JULIUS, COUNT (1835- ), Hungarian statesman, son of the former Minister of the Interior, was born June 30 1860. Deputy (1885), Secretary of State for the Interior (1892), Minister of the Court (1894), he became Minister of the Interior in 1898. As Minister of the Interior, as well as earlier in connexion with the language of command in the Hungarian army and against the régime of Fejervary, he maintained a severe struggle with the prime ministers Khuen-Hedervary and Stephen Tisza. In 1913 he delivered three speeches in the Hungarian Delegation against the conduct of foreign affairs, and in Parliament he opposed the plan for the centralization of the internal administration of Hungary. At the outbreak of the World War he supported the Tisza ministry, but opposed Burian, the Foreign Minister, on the Polish and the Italian questions. In 1915 he pleaded for peace, and urged a wide cession of the franchise. In 1918, as Foreign Minister, he declared the alliance with Germany dissolved, and desired to conclude a separate peace. He retired from office on Nov. 5, was returned for Miskoloz to the National Assembly in Jan. 1920 as a non-party delegate, and later became leader of the Christian National party. In 1904 he was made an associate of the Hungarian Academy of Sciences, in recognition of his distinguished work as a historian.

His works include: Ungarn Ausgeleug vom Jahre 1867 (Hungarian and German, crowned by the Academy); Die Ursachen des Bestandes des Ungarischen Staates und dessen verfassungsmäßiger Freiheit (3 vols., Hungarian, crowned by the Academy); Der Entwurf des Grundgesetzes für den Zentralstaat; Die Entwicklung der Ungarischen Verfassung; Das Verhältnis der Ungarn in Holland und in England; Die Entwicklung der Verfassung der Ungarn in den Jahren 1848-67; and many other works and addresses on Hungarian history and politics.

ANDREE, RICHARD (1853-1912), German geographer (see 1.971), died at Leipzig Feb. 22 1912.

ANGEIL, JAMES ROWLAND (1860- ), American educator, was born at Burlington, Vt., May 8 1860. He was a son of James Burrill Angell (d. 1916), first president of the university of Vermont, and a brother of the late Edward C. Angell. He was educated at the universities of Michigan (A.B. 1880; A.M. 1891) and Harvard (A.M. 1892), and spent a year in Europe, chiefly in Berlin and Halle. In 1913 he was appointed professor in philosophy at the university of Minnesota. In 1894 he was called to the university of Chicago, remaining there until 1912, as assistant professor of psychology and director of the psychological laboratory, associate professor and, after 1905, professor and head of the department. He was dean of the university faculties after 1911 and acting president during 1918-9. In 1906 he was elected president of the American Psychological Association, in 1914 was exchange professor at the Sorbonne, and in 1915 was special lecturer on psychology at Columbia. After America entered the World War in 1917 he was connected with the adjutant-general's office as member of the committee on classification of personnel in the army. He was also a member of the National Research Council, serving as chairman during 1919-20. In April 1920 he was elected president of the Carnegie Corporation of New York. In 1921 he was elected president of Yale to succeed Arthur T. Hadley, resigned.

He was the author of Psychology (1904; 4th ed. revised, 1908); The Philosophy of Aristotle (1912) and An Introduction to Psychology (1918).

ANGOLA (Portuguese West Africa) (see 2.38).—A census taken in 1914 gave the pop. as 2,124,000, but this total was based on figures supplied by the natives for the purpose of a hut tax,
ANNUNZIO, GABRIELE D': ANTARCTIC REGIONS

Kunene river valley, part of which was in German territory, was inhabited by the Ovambo, of whom some 20,000 were recruited by the Germans for work in the Otavi copper-mines. In 1913 the Portuguese forbade further recruiting in Angola; the Germans replied by presenting estimates to the Reichstag in 1914 for £50,000 towards building a railway from Otavi through the Ovambo country and 22 m. of the railway had been built when the World War began. Though Portugal was at the time neutral several conflicts occurred between the Portuguese and Germans in the frontier district. The surrender of the Germans in South-West Africa to Gen. Botha, in July 1915, removed the German occupation of Angola and limited the province of the British (South Africans) as neighbours on the south.

In an endeavour to break with the tradition that the colonies existed only for the benefit of Portugal the Lisbon Government in 1914 granted them a measure of autonomy. The then governor-general of Angola, Senhor Norton de Mattos, had already instituted reforms and in 1913 had created a Department for Native Affairs, which set itself to regulate the employment of natives, including the recruitment of labourers for the cocoa plantations on St. Thomé and Principe Islands. The result was some improvement in the attitude of the natives towards compulsory labour was maintained, and abuses continued.

In 1920 Portugal again endeavoured to set its colonial affairs in order. Another autonomy measure was introduced and Senhor Norton de Mattos was again (Oct. 1920) selected to go to Angola, this time as high commissioner with wide powers.

ANSON, SIR WILLIAM REYNELL, 1ST BART. (1843–1914), English jurist (see 2.84), died at Oxford June 4 1914. In 1900 he signed the minority report of the Divorce Commission, in company with the Archbishop of York and Sir Lewis Dibdin.

ANTARCTIC REGIONS (see 21.960).—The expedition planned by Dr. W. S. Bruce for crossing the Antarctic continent in 1911–2, from Coats Land on the Weddell Sea to McMurdo Sound in the Ross Sea, was not proceeded with, and two American expeditions which were contemplated at the same time did not advance beyond the stage of projects.

Shirase (1910–2).—A Japanese expedition to Edward VII Land, from which a party under the command of Lt. Shirase in 1910 and left Japan in that year on board the "Kaiman Maru." It entered the Ross Sea too late to make a landing, and after wintering in Sydney returned in 1911–2, when a landing was effected on the Barrier in the Bay of Whales on Jan. 16, but no discoveries were reported and no account appears to have been published in any European language.

Amundsen (1910–2).—Capt. Roald Amundsen sailed from Norway in the "Fram" (which had been fitted with internal combustion engines) in Aug. 1910 with the avowed intention of carrying out oceanographical work in the South Atlantic and of proceeding round Cape Horn to Bering Strait, where he proposed to repeat Nansen's drift across the Arctic sea from a more easterly starting-place. The announcement of Peary's attainment of the North Pole in 1909 convinced Amundsen that he could not raise sufficient funds for his proposed five years' absence, and he determined to make a dash for the South Pole in order to raise money for the greater project. His change of plan was announced to the world at Madeira in Sept., and on Jan. 14 1911 the "Fram" was alongside the Barrier in the Bay of Whales, lat. 77° 40' S. long. 165° W. The 11 Eskimo dogs were landed and a hut, "Frameheim," erected on the Barrier 21 m. inland, at the point of departure for the Pole being that originally proposed by Shackleton in 1907. On Feb. 15 1911 the "Fram," under Lt. Thorvald Nilsen with nine men, sailed for an oceanographical circumnavigation, with Buenos Aires as the first port of call. Amundsen started on his first depot-laying journey on Feb. 10, and by April 11 had moved 3 tons of provisions to three
deposits in 80°, 82° and 82° S., respectively. A start for the main south journey was made on Sept. 8 but the cold proved too severe (−58° to −75° F.) for the dogs and the party returned to winter quarters for a month. On Oct. 20 1911 (with temp. −5° to −23° F.) Amundsen left again with four companions, Helmer Hanssen, Oscar Wisting, Sverre Hassel and Olav Bjaaland, four sledges and 52 dogs. At each original depot they rested a day and gave the dogs a full feed from the stores; but on Nov. 8 they left the depot in lat. 82° S., carrying four months' provisions and having about 50 m. a day over the smooth Barrier surface, the men using ski. At every degree of latitude the sledges were lightened by forming a depot of provisions for the return journey. On Nov. 9 the mountains of South Victoria Land were sighted, and on the 11th another range of mountains was seen joining the Victoria Land range from the direction of Edward VII. Land, and thus forming the southern boundary of the great flat Barrier surface, which apparently did not extend far beyond lat. 85° S. On Nov. 17 a large depot was left in lat. 85° S. at the base of the Queen Maud range which formed the continuation of the Victoria Land mountains, at a point 200 m. S. of the Beardmore glacier. From this point the climb to the Plateau began through magnificent scenery of glaciers and peaks, the heights of which were estimated as 10,000, 15,000 and even 10,000 feet. A way was found to the summit of the Plateau by the Axel Heiberg glacier which was negotiated by the dogs with much difficulty. Four days were occupied in the ascent to a level stretch at 7,000 ft.; and severe weather compelled a halt at this point for four days more. Here 24 dogs were killed, leaving 18 to work the three sledges. A start due S. was made on Nov. 26 and for two days severe blizzards made it impossible to see the surroundings, but the course lay on a descending gradient. On Nov. 29 a depot with six days' provisions was made at the foot of the Devil's glacier in lat. 86° 21' S. On Dec. 1 at a height of about 9,000 ft. the way led over a smooth ice surface on which it was impossible to use ski, while under the tread it sounded like walking on empty barrels, and both men and dogs frequently broke through the thin crust of ice. This tract, called "The Devil's Ball Room," proved the worst travelling of the whole trip. Next day in lat. 88° S. the highest swell of the Plateau, estimated at 11,000 ft., was passed and in a few days the weather improved, travelling was easy, and on Dec. 14 1911 the position of the South Pole was reached. The total distance from Framheim of about 870 m. was accomplished in 30 days' actual travelling time, the average being 17 miles. After remaining two days at the Pole to secure sufficient observations to fix the position, Amundsen and his party returned to Framheim in 38 days, picking up the depots in succession and making an average of 25 m. per day in fine weather without any untoward incident. The health of the men and the 11 surviving dogs was perfect throughout the 96 days of the double journey. During the absence of the southern party Lt. K. Prestrud with Frederik H. Johansen and Jørgen Stubberud made a journey to Edward VII. Land with two sledges and 14 dogs. They were absent from Framheim (where Lieutenant the commodore was left in charge) from Nov. 8 to Dec. 16 1911 and reached Scott's Nunnatak, which was found to reach a height of 1,700 ft. and was covered with thick moss. The "Fram" returned to the Bay of Whales on Jan. 11 1912 and the whole party sailed for home on Jan. 30, after the shortest and most successful expedition which ever wintered in the Antarctic. The one object, the attainment of the Pole, had been accomplished quickly and easily and the meteorological observations were of great value in extending the conclusions of other investigators.

Scott (1910-2).—Capt. Robert F. Scott's expedition, planned with 40 days' actual travel, was the first to try to reach the Pole and completed the scientific study of the Ross Sea area, reached McMurdo Sound in the "Terra Nova" on Jan. 4 1911 (after seeking in vain for a safe position near Cape Crozier), and erected a commodious wooden house for the main base at Cape Evans on Ross Island, about half way between Shackleton's base at Cape Royds and the old "Discovery" headquarters at Hut Point. No polar exploration had been fitted out with greater care for the purpose of scientific research in meteorology, geology, glaciology and biology. After landing the stores for the main base at Cape Evans the "Terra Nova," under Comm. Harry Pennell, left on Jan. 29 1911, proceeded eastward along the Barrier and, after failing to land on Edward VII. Land, encountered the "Fram" in the Bay of Whales on Feb. 3.

Scott's Northern Party (1911-2).—The eastern party decided to return with news of the Norwegian expedition to Cape Evans, and then to proceed as a northern party to some point beyond Cape North, but this also proved unattainable, and a landing had to be made at Cape Adare on Feb. 18 1911. Here a hut was erected with the name of the party under Comm. Victor L. A. Campbell and including Surg. Gen. Murray Levick, Raymond E. Priestley (geologist and meteorologist) petty-officers G. F. Abott, F. V. Browning and H.Dickson, were landed with stores and sledges but no dogs. One of Borchgrevink's huts built in 1899 was in good order, the other had been unroofed by a storm but both were serviceable. They passed a stormy winter and confirmed Borchgrevink's conclusion that it was impossible to make any extensive journeys either on the sea-ice, which frequently blew out to sea, or by land from this base. On Jan. 4 1912 the "Terra Nova" returned and took off the party, landing them with six weeks' provisions but a few days later in Terra Nova Bay, just S. of Mt. Melbourne, on the lower slopes of which much geological work was done. The ship failed to return in Feb. as expected, and the winter of 1912 had to be passed in an ice cave on Inexpressible I. (about lat. 75° S.), the party subsisting mainly on seal meat cooked over blubber lamps devised with much ingenuity. This winter, spent almost without stores, was a triumph of adaptability to the hardest possible conditions, and although there was much illness the whole party was able to march when a start for Cape Evans was possible on Sept. 30 1912. The Drygalski glacier tongue was crossed and the party made its way southward along the sea-ice close to shore. On Oct. 28 Granite Harbour was reached and stores left there by Griffith Taylor allowed of full rations of good food for the first time for nine months. The remainder of the 70-m. march to Cape Evans was assisted by several depots, and they all arrived at Hut Point on Nov. 6 1912, after triumphing over the most difficult conditions ever yet surmounted in the Antarctic.

Scott's Western Party (1911-2).—During Jan., Feb. and March 1911 Griffith Taylor, with Frank Debenham, Charles S. Wright and P. O. Edgar Evans, made an extensive geological survey and study of the ice phenomenon of the lower valleys of the Western Mountains, from Butter Point southward to the Koettzli glacier in lat. 78° 20' S., and after the winter at Cape Evans, Griffith Taylor made a second western trip with Debenham, Lt. Tryggve Gran and P. O. Forde, completing the geological survey of the lower mountain slopes W. of McMurdo Sound from Butter Point northward to Granite Harbour in lat. 76° 50' S. This journey lasted from Nov. 1911 to Feb. 1912 and was rich in scientific results.

Wilson's Winter Journey (1911).—The finest adventure of the first winter at Cape Evans was the daring journey in solstitial darkness via Hut Point to Cape Crozier and back by Dr. Edward A. Wilson, Lt. H. R. Bowers and Mr. Apsley Cherry-Garrard. It lasted for 36 days from June 27 to Aug. 1 1911, and the total distance travelled by man-hauled sledges was over 100 m., giving an average of about 4 m. per day out and 7 m. a day home. During a stay of ten days an effort was made to study the nesting habits of the emperor penguin. This journey was made in the lowest temperature ever experienced in the Antarctic: many days had readings below −60° F. and the worst was as low as −77° F. The snow in places was as granular and hard to pull through as sand, and only one sledge could be moved at a time, so that on some days 'men's' work only made 2 m. in distance.

Scott's Journey to the South Pole (1911-2).—The main object of Capt. Scott's expedition being the great southern journey, steps were taken at the earliest date to lay out depots for the main expedition of the following year. The vital point being transport, means had been taken to provide three alternatives to man-haulage. There were landed at Cape Evans 17 Siberian
ponies, 33 Siberian sledge dogs and three motor sledges on the design of which Scott had taken immense pains. The motors were practically useless on account of mechanical defects and were abandoned early in the great march. The health of the animals was a source of unending anxiety and much trouble was experienced in driving them.

The route selected was at first about a day's march to the E. of that taken by Shackleton and consequently to the E. of the line followed by Scott on the "Discovery" expedition, the reason being to get the smooth Barrier ice beyond the influence of the great pressure ridges which disturb the surface near the mountains. But the Plateau was to be reached by Shackleton's way up the Beardmore glacier at which point the tracks converged.

Depots were laid out by Scott in Jan. and Feb. 1911 at Corner Camp in lat. 78° S., Bluff Camp nearly in lat. 70° S. and at One Ton depot which he had hoped to plant in lat. 80° S., but was obliged by circumstances to place in lat. 79° 29′ S.—only a necessity which contributed to the greatest Antarctic disaster on record. In Sept. 1911, when the temperature was usually below -40°F., Scott's servant, Lt. Edward R. A. Evans, took additional stores to Corner Camp; but no more distant depots were supplemented before the main southern journey started.

The two motor sledges left Cape Evans on Oct. 24 1911, got over the sea-ice to Hut Point, safely ascended to the Barrier and broke down hopelessly, the first a few miles N. of Corner Camp, the second a few miles S. of Corner Camp on Nov. 3. Thenceforward the southern advance was made by 16 people in three parties of four each, reinforced by two from the motor sledges and two who开车离开 the party ahead breaking the trail, the others following at intervals. Bad weather was experienced, frequent blizzards making the advance difficult. Depots with stores were provided for the returning parties at Mount Hopeo in lat. 80° 35′ S. on Nov. 21 (Day and Hooper of the motor party, who had dragged a sledge so far, left to return three days later), at the Mid Barrier in lat. 81° 35′ S., at the South Barrier depot in lat. 82° 47′ S. on Dec. 1 and at the entrance to the Beardmore glacier in lat. 83° 30′ S. on Dec. 10. The last of the ponies had been broken down and been shot, and from this point Meares and the dogteams returned northward. The party of 12 pushed up on the Beardmore glacier with three-man-hauled sledges, and after leaving a depot in the middle of the glacier, reached the Plateau at 8,000 ft. on Dec. 21 1911 and left the Upper Glacier depot in lat. 83° 4′ S. Here Dr. Atkinson, Mr. Wright, Mr. Cherry-Garrard and P. O. Keohane returned, and the party of eight went on with two sledges. Ten days later Three Degree depot was formed in lat. 86° 50′ S. and at this point Lt. Evans with Crean and Lashly returned. This party was attacked by scurry as on the southern march from the "Discovery" in 1902, and Lt. Evans broke down on the Barrier and was only rescued by the heroic exertions of his companions. The southern party—now consisting of five men: Scott, E. A. Wilson, H. R. Bowers, L. G. Oates and P. O. E. Evans—made one more depot in lat. 88° 29′ S. and reached the South Pole on Jan. 18 1912, having made 69 marches averaging over 12 m. per day. His diary shows that in the outward journey Scott's mind was full of care and anxiety, while the disappointment of finding by Amundsen's record that he was not first to reach the Pole was a shock from which his spirits seemed never to recover.

The return journey was commenced without delay, but without any help from animal traction it proved too much for the men. Edgar Evans, the first, and after changing tent delaying, he died on Feb. 17 on the Beardmore glacier. Oates, feeling his strength exhausted, had the heroism to sacrifice himself rather than cause further delay, and he left the tent on March 17 in 79° 50′ S. never to return. The last camp was made in lat. 79° 40′ S., only 11 m. from One Ton depot on March 19, and here during a blizzard which raged for several days Scott, Wilson and Bowers met their fate with heroism, Scott writing to the end. The immediate cause of collapse seems to have been cold, due to the deficiency of oil fuel in the Mount Hopeo depot, the reason for which was stated to be evaporation through defective stoppers.

The Winter of 1912 at Cape Evans.—During the absence of the southern party the "Terra Nova" had reached Cape Evans in Feb. 1912 and stores were landed, including seven miles from India and 14 dogs. Dr. Atkinson's party, sent back by Scott from the Beardmore Glacier, arrived on Jan. 28, and after seeing matters at the base, Dr. Atkinson went south with the dogteams in time to rescue Lt. Evans near Corner Camp on Feb. 22, and as the latter was in a serious condition Atkinson stayed with him until he got him the board of the "Terra Nova." Cherry-Garrard and Dimitri took the dogteams back to One Ton depot to meet Scott, reaching that point on March 4 and remaining until March 10 in weather that made a further advance S. impossible, and they got back to Hut Point on the 16th with great difficulty and in a very bad state. The ship left on March 8 to make a final attempt to relieve Campbell's northern party and did not return, so the base party did not know what had happened either to the northern or southern parties. On March 26 Atkinson with P. O. Keohane set out from Hut Point and got as far as Corner Camp, where he turned, being satisfied that Scott's party must have perished. He made one more journey, though it was now very late in the season, and left two weeks' provisions at Butter Point for the northern party, returning to Hut Point on April 23, the day the sun disappeared for the winter. There were 13 souls in the Cape Evans hut that winter, with Dr. Atkinson in charge, Lt. Evans having returned ill to New Zealand and Dr. G. C. Simpson, whose meteorological work had been of unique value, having gone back to his duties in India. On Oct. 30 1912 the whole party, under Dr. Atkinson, with Mr. C. S. Wright as guide, with seven miles and the dogs, set out from Hut Point and on Nov. 12 the tent with the bodies of Scott, Wilson and Bowers was discovered in lat. 79° 50′ S., and the records and collections brought back.

During Dec. 1912 a party of six climbed Mt. Erebus, reaching the summit on the 11th, the second occasion of its ascent.

The"Terra Nova" returned on Jan. 18 1913 and a few days later took off the entire party, reaching New Zealand on Feb. 12. The sensation produced by the tragedy of the expedition was profound and a large fund was subscribed for the benefit of the relatives of the dead explorers and for the promotion of polar research. The scientific results of the expedition have been worked up and are of the highest value in all departments.

Australian Expedition (1911-2).—An Australian expedition was fitted out under the command of Dr. (later Sir) Douglas Mawson, with Capt. John King Davis as commander of the ship and second-in-command of the expedition, for the purpose of exploring the coast of Antarctica S. of Australia. The expedition left Hobart in the "Aurora" on Dec. 2 1911, and after landing a party with a wireless installation on Macquarie I. (lat. 55° S.) the ship reached Adelie Land, discovered by D'Urville in 1840, and effected a landing in Commonwealth Bay, the position of which was subsequently fixed by wireless time-signals as lat. 69° S., long. 142° 40′ E. Dr. Mawson with 17 companions was landed here in Jan. 1912. The "Aurora" proceeded westward close along the Antarctic circle. Balleny's Sabrina Land, D'Urville's Côte Clarie and most of the land reported by Wilkes were found not to exist, though an enormous ice-ridge which might well have been taken for part of the continent occupied the position of Termination Land. Just beyond this point Mr. Frank Wild was landed on a new coast called Queen Mary Land in lat. 66° S., long. 94° E., and left with seven companions on Feb. 9 1912; the actual position being given as 68° 17′ S., long. 97° 17 m. from the high land. The "Aurora" returned to Hobart.

At the main base in Adelie Land autumn sledding proved impossible, and throughout the winter there was a continuous succession of terrific blizzards, wind with an average velocity of 50 m.p.h. for the year, and sometimes with average hourly velocity of over 100 m.p.h. poured torrents of drift snow from the interior into the sea. Only the fact that the hut was buried in the snowdrifts saved it from being carried away. No such weather has been recorded from any other part of the world. In the spring two caverns were excavated in the ice at distances
of about 5 and 12 m. respectively from the hut towards the high inland plateau and were stored with provisions for summer sledging; the use of surface deposits like those on the Ross Barrier was impossible owing to the wind. Five sledging parties started simultaneously in Nov. 1912, their paths diverging so as to cover the greatest possible area. The eastern sledging parties under Mr. F. L. Stilwell and C. T. Madigan with Dr. A. L. Maclean and others, mapped the Queen Maud glacier terraces as far east as long. 105° E. reaching the farthest point on Dec. 18. The land, with a surface rising to 3,000 ft. above the sea, extended far to the east and was named George V. Land. It stretched towards Oates Land sighted by the "Terra Nova" of Scott's expedition. Good rock exposures were found containing coal and fossils. The magnetic pole party from the main base, under Lt. R. Bage with E. N. Webb and J. F. Hurley, travelled out 300 m. with man-hauled sledges and reached 6,500 ft. above sea-level at a point only a few miles from that reached by Sir Douglas Mawson and Sir Edgeworth David from McMurdo Sound on Sir Ernest Shackleton's expedition. The western party, led by Mr. F. H. Bickerton, with A. J. Hodgeman and Dr. L. A. Whetter, reached a point on the Antarctic circle in long. 138° E. on Christmas Day, travelling over the Plateau at a height of about 4,000 ft. An air tractor sledge started with this party but broke down after 10 miles.

Dr. Mawson, with Dr. X. Mertz and Lt. B. E. S. Ninnis, using dog sledges, set out for a long journey to the S. E. well inland of Madigan's party, and had very difficult ground to cover, including many rises to over 3,000 ft. with intermediate descents to near sea-level, where there were heavily crevassed glaciers. They had got out 3,400 m. to nearly long. 15° E. when on Dec. 14, 1912 Ninnis, with his sledge and dogs, broke through the snow covering of a crevasse of enormous depth and was instantly killed. Many essential parts of the equipment were lost with the sledge, and only six dogs in poor condition were left. From this point the homeward track was laid farther S. than the outward so as to avoid the great ups and downs, and the travellers pushed on in frequent bad weather on short rations supplemented by the flesh of the dogs. Both suffered severely from the insufficient and loathsome food, and Mertz collapsed on Jan. 6 1913 and died the following day, leaving Mawson alone 100 m. from the main base. After three days spent in cutting down the sledge and rearranging its load Mawson started on his lonely tramp, and after appalling difficulties, when nearly exhausted, he stumbled on a food depot laid out by a search party 20 m. from the hut on Jan. 20 1913. It was Feb. 8 when he reached the hut and saw the "Aurora," but she was outward bound. A fresh relief party had come S. in the ship, and a second winter had to be spent in the hut, the isolation somewhat mitigated by wireless intercourse with Australia via Macquarie Island.

Capt. Davis, after landing the relief party and taking off all the others, waited for the return of Mawson as long as he dared, having in view the necessity of relieving Wild's party in Queen Mary Land, and the fact that every anchor on the ship had been lost in the fight with blizzards in Commonwealth Bay. He reached Wild's base just in time, got the party safely on board and returned to Hobart. From their base in long. 98° E. Wild's party had travelled W. to the Gaussberg in long. 89° E., and E. as far as long. 103° E., mapping the glaciers which descended from a plateau rising above 3,000 ft., as well as several islands off the coast. The "Aurora" returned to Commonwealth Bay on Dec. 15 1913, and after taking the base party on board made another voyage to the northern coast of Queen Mary Land. The "Deutschland" proceeded along the new coast, named Lützow Land, to lat. 77° 49' S., long. 35° W. on Feb. 2 1913, where an indentation in the Barrier ice formed Vahsel Bay, whence the land rose to the S. and three nunataks were observed piercing the snow. Efforts to get farther S. on a westerly course failed, and on Feb. 6 it was decided to erect the winter hut on an iceberg which appeared to be firmly frozen to the Barrier and to offer an easy passage for dog-sledges to the land. All stores were transferred to the iceberg, when on Feb. 18 it suddenly began to move and ponies, dogs, stores and as much of the wood as could be saved were hurriedly reembarked. Two small depots of provisions were afterwards laid out on the Barrier ice as a base for land parties while the ship sought for winter quarters; but Capt. Vahsel feared the destruction of the vessel, and induced the leader to change his plans and return to South Georgia for the winter in order to try again next year. The return journey was commenced on March 4 1912, but four days later the ship was beset by young ice in lat. 74° S., long. 31° W., and remained fast, drifting with the winds and currents of the Weddell Sea all winter, on the whole westward and northward until the middle of August, when the "Endurance" was drifted eastward and northward until she broke out of the pack in lat. 63° 40' S. and long. 36° W. on Nov. 27 1912 and proceeded for home. The drift lasted for 26 days and no land was sighted, although a sledge journey was made westward to long. 45° W. in search of Morrell Land. Capt. Vahsel died during the drift, and the expedition broke up at South Georgia.

Shackleton's Weddell Sea Party (1914-6).—Sir Ernest Shackleton had completed his preparations for an attempt to cross the Antarctic regions from Weddell Sea to Ross Sea before the outbreak of the World War, and entrusted his expedition at the direct order of the Admiralty, which declined his offer of the ships and men for war service. He left England on Aug. 8 1914 in the "Endurance" and sailed from South Georgia on Dec. 5, with the intention of landing in Vahsel Bay and proceeding thence to the South Pole after wintering on the land. The pack was entered in lat. 57° S. and the ship worked her way S. between long. 15° and 26° W. until on Jan. 11 1915 she sighted Coats Land, and followed new land named the Caird Coast to Lützow Land. Here the "Endurance" was beset in the ice on Jan. 18 in lat. 76° 34' S., long. 31° 30' W. and the voyage was at an end. The "Endurance" had done three years before, and on a nearly parallel track, moving N. about 10° farther W. and at almost exactly the same rate in the same latitudes. The ice was however much heavier, and in the terrific pressures which occurred the "Endurance" was crushed on Oct. 27, when the expedition of 28 men with 49 dogs abandoned her and camped on the floe. This was in lat. 69° 5' S., long. 51° 30' W., and three weeks later the shattered wreck sank through the ice. The attempt to sledge over the ice towards the E. coast of Graham Land was unavailing, as the ship's boats could not be left behind and were too heavy to drag. The party therefore camped on the drifting floe, keeping up scientific observations and maintaining their health and spirits though in continual danger from the floes ridging up or cracking asunder. The drift went on until April 9 1916 when the floe, reduced to a triangle 200 yds. in the side, drifted into the open sea in lat. 62° S., long. 54° W., and the party had to take to their boats, after drifting 202 days in the ship and 165 on the bare ice, 437 days in all. North of lat. 66° S. the drift of the "Deutschland" had turned sharp to the E., but that of Sir Ernest Shackleton's floe continued in the main due N.; the difference may have been due to the operation of local ice currents. The two boats safely reached Elephant L. in the South Shetlands, and a shelter was rigged up of two boats, where 22 of the party were left under the capable leadership of Mr. Frank Wild, while Shackleton and five companions set out in the third boat, the "James Caird," for the almost desperate attempt to reach South Georgia. The effort succeeded in great measure through the fine seamanship of Capt. Worsley, and the island was reached in 16 days on May 10 after a voyage of over 800 m., but on the side farthest from the whaling stations. After a four-days rest Shackleton, with two companions, had recovered sufficiently to cross the unknown snow-covered mountains, which had never
been climbed before, and a steamer was sent round for the others. Sir Ernest Shackleton made strenuous efforts to rescue the Elephant I. party first in a small steamer from South Georgia, then in a trawler from Montevideo, and in little motor schooners from Punta Arenas, all of which were driven back by the ice floes near the South Shetlands, and finally in the "Yelcho," a tug from Punta Arenas, in which he reached the island on Aug. 30, 1916 and brought back the whole party without a casualty. Shackleton's Ross Sea Party (1914-7).—On the Ross Sea side, the "Alexander" under command of Capt. Aeneas Mackintosh, brought an auxiliary expedition to lay out depots on the Barrier to facilitate the latter part of Shackleton's march from the Weddell Sea via the South Pole. The "Aurora" reached Cape Evans on Jan. 16, 1915, and while she remained there with the hope of wintering, Mackintosh and a sledge party laid out depots as far as lat. 80° S. by Feb. 20. This was a better record than in Scott's autumn journey of 1911; but it was midwinter before Mackintosh found the ice strong enough to permit of his return to Cape Evans. Early next summer he started again; was at the 80° depot on Jan. 6 1916 and with five companions reached Mt. Hope at the mouth of the Beardmore glacier in lat. 83° 36' S. on Jan. 20 where he left a depot. The return journey was one of terrible hardship aggravated by scurvy, and the party narrowly escaped Scott's fate. Mr. Spencer Smith died, but the rest reached Hut Point on March 18 1916. In their anxiety to get back to the Cape Evans party, Mackintosh and Hayward attempted the journey on the sea-ice on May 8, but the ice was not strong enough and they were lost. It was July before the rest of the southern party reached Cape Evans.

On May 6 1915 the "Aurora," which had been frozen in and made fast by many cables to the shore at Cape Evans, was blown out to sea with all the ice and was held fast for 315 days, during which time she drifted northward through Ross Sea nearly in the same direction and at nearly the same rate as the "Endurance" was drifting at the same time in the Weddell Sea. She had been severely damaged by ice pressure; but Lt. J. R. Stenhouse, who was in command, rigged a new rudder, and when she was released on March 16 1916 in lat. 65° 27' S., long. 157° 30' E., he brought the disabled vessel safely to New Zealand. The ship was repaired by the New Zealand Government and dispatched under the command of Capt. J. King Davis with Sir Ed. Hillary on board, and on Jan. 17 1917 she reached Cape Royds and rescued the few men who had come safely through their two winters in spite of shortage of supplies, the winter stores not having all been landed when the ship was blown away. All of the 53 men who returned from the expeditions of the "Endurance" and "Aurora" served in the navy, army or air force during the World War, three being killed and five wounded.

Scientific Results.—The scientific results of the expeditions described above could not yet in 1921 be adequately summarized, for the war had retarded the investigation of the collections and the discussion of statistics. It would be impracticable to draw general conclusions as to the physical and biological conditions of the Antarctic regions until the researches of all the expeditions had been published in a comparable form.

All the influences from earlier work required revision, but specialists of different expeditions had already committed themselves to views which could not be reconciled in the absence of full information from all explorers. This observation applies in particular to the general theory of the meteorology of the South Polar area, as expounded for the Gauss expedition by Prof. Meinardus and for Scott's last expedition by Dr. G. C. Simpson. The results of the Australian and New Zealand expeditions, which were at the expense of the time synchronous with those of Scott and Amundsen, required to be taken into consideration before a general theory of the atmospheric circulation within the Antarctic circle could be established. This is also the case as to geology, and the bearings of geological evidence on the probable nature and extent of the Antarctic continent, and the relations of that land mass to the other continents.

See, in addition to the books referred to in the 11th ed., R. Amundsen, The South Pole (two vols. 1912); L. Huxley, Scott's Last Expe-

dition (two vols. 1913); R. E. Priestley, Antarctic Adventure, Scott's Northern Party (1914); G. Taylor, With Scott, the Silver Lining (1916); Sir A. Hayward, The Home of the Blizzard (two vols. 1915); J. E. Davis, With the "Aurora" in the Antarctic (1920); Sir E. Shackleton, South (1919).

ANTHROPOLOGY.—The earlier article (see 2:108), discussing the problem of man's origin and the possibility of recovering fossils which would throw further light on early types of man, included the remarkable statement: "It seems as if anthropology in this direction reached the limits of its discoveries." This prediction has unfortunately been stultified almost every year since it was made, for later years have yielded an abundantly rich harvest of anthropological data and a clearer vision of their significance. In fact they have witnessed a profound revolution in every branch of the study of man. New and important work has been acquired concerning man's ancestry, and the factors that brought the Primates into existence and transformed one branch of the Order into the human family. Hitherto unknown types of fossil men have been found in the Maurer Sands near Heddleberg, at Piltdown in Sussex, at Talgat in Queensland, at Wadjak in Java and at Boskop in the Transvaal. So many examples of Neanderthal Man have been found at Le Moustier, La Chapelle-aux-Saints, La Quina, La Ferrassie, in Jersey and near Weimar, that we are now able to get a very clear idea of the appearance and distinctive features of the brutal species of man that preceded Homo sapiens in Europe. Much new information has been acquired of the different races of Homo sapiens that made their way into western Europe after Homo neanderthalensis disappeared from the scene; and the discovery of their paintings on the walls of caverns in southern France and in Spain and their plastic art has been an astounding revelation of the genius and skill of these primitive men. The artistic feeling of these earliest known members of the species to which we, and all men now living, belong.

The brilliant researches of French anthropologists have made it possible to classify the phases of culture of the so-called upper palaeolithic age and assign to each distinctive features and its chronological sequence with reference to the other phases. Intensive studies of the older civilizations of Egypt, Elam, Sumer (and Babylonia, which succeeded it), Crete, the Aegean, Palestine, Syria and Asia Minor, have made it possible to understand the origin of civilization in a way that was undreamt of hitherto; and it is perfectly possible to depict the rise of modern civilization in a broad perspective; whereas, hitherto, the common civilization was diffused into Europe, to Turkestian and India, to Siberia and China, to Indonesia and Oceania, until finally it crossed the Pacific to Central America and Peru. But perhaps the most profound change that was initiated in anthropology during the decade 1910-20 was the demolition of many of the dogmas which for half a century had paralyzed ethnological investigation and prevented those who were collecting the evidence from appreciating its real significance. This fundamental change of view had not in 1921 been generally accepted by ethnologists, but there were already very obvious signs that many of them were preparing to repudiate the fashionable doctrine, which had been expressed in its most extreme form in the earlier article in this Encyclopaedia.

The Evolution of Man.—In spite of not infrequent attempts to disprove man's kinship with the apes, recent research in anatomy, embryology and comparative pathology, as well as the conclusive tests of blood-relationship, has definitely established the fact of man's close kinship with the anthropoid apes, and especially with the gorilla. But this fundamental conclusion is not in any sense invalidated by the clear recognition of the fact that the gorilla and the man are two distinct kinds of animals, the gorilla respectively became differentiated from the other at least as early as the middle of the Miocene period. This does not mean that man's forebears assumed their human characteristics at the period mentioned, but rather that the ancestors of the gorillas and chimpanzees had begun to assume their distinctive specializations and to fall out of the race for intellectual supremacy which was eventually to be attained by the descendants of their unespacialized Miocene brothers. It is in the highest degree
probable that throughout the Miocene, man's ancestors were still simian. All we know of them is that certain fossil apes found by Dr. Pilgrim in the foothills of the Himalayas reveal curious little peculiarities of structure that serve to identify them in his opinion as members of the group of anthropoids from which the hominidae were eventually derived—probably not until the latter part of the Pliocene (G. E. Pilgrim, "New Siwalik Primates," Records of the Geological Survey of India, xlv., 1915). But whether or not Dr. Pilgrim is justified in his claim that the newly discovered Miocene ape which he has called Eoanthropus is the ancestor of man or not, it is quite clear that the times when the first man-like creature made its appearance were a great breeding-ground of anthropoid apes, and that the great variety of species and genera which were evolved there included the ancestors not only of the orangs, the chimpanzees and gorillas, but also of the human family. The ancestors of the chimpanzees and gorillas spread west with man's forerunners and reached not only Africa, where their descendants have survived until the present day, but also Europe where the fossilized remains of Dryopithecus are widespread. In the course of its wanderings between northern India and Africa human characteristics emerged in one of these simian representatives. The first difference between the earliest member of the human family and his simian cousin was the fact that his brain had developed a little further than the ape's, so that he was able to learn to perform acts of a higher degree of skill not only with his hands but with his vocal muscles. He had acquired the power not merely of a fuller appreciation of the symbolism of sound, but also of arbitrarily imitating sounds and of creating a vocal symbolism whereby he could learn from his fellows and communicate his ideas to them. It was the enormously enhanced power of acquiring knowledge and profiting from the experience of his fellows that differentiated man from the apes; and the peculiar features of the endocranial casts of the fossils Pithecanthropus and Eoanthropus suggest that the acquisition of the power of speech may have been an essential part of the process of making a man from an ape.

If India has provided us with new light on the place and time of the separation of man's ancestors from the other apes, Egypt has revealed the origin of the anthropoids. It was in 1901 that Dr. C. W. Andrews, of the British Museum, discovered that the Egyptian Fayum was a veritable museum of hitherto unknown fossil ancestors of some mammalian Orders. His publications, indicating the great number of mammal fossils which have been fully realized by the discovery of the very primitive Cata rhine Parapithecus and an anthropoid ape, Propliopithecus (M. Schlosser, "Beiträge zur Kenntniss der Oligozän-und Miozän- Tier aus dem Fayum [, Ägypten,", Beiträge zur Pal. u. Geol. Öster reich-Ungarns u. d. Orient, Bd. xxiv., 1911). The discovery of a diminutive anthropoid as early as the beginning of the Oligocene period prepares us for the fact that it presents many signs of not distant kinship with the peculiar Eocene Tarsiodae, a Sub-Order of Proboscidea, one of whose members, the Spectral Tarsier, still survives to-day in the forests of Borneo, Java and certain other islands of the Malay Archipelago. For some years intensive studies have been made of the anatomy and embryology of this remarkable creature (see, for example, "The Discussion of the Zoölogical Position and Affinities of Tarsius," Proc. Zool. Soc. London, 1910, published Feb. 1920); and these investigations have shed a great deal of light upon the factors that brought the Primates into being and in one group of the Order initiated further changes, especially in the cultivation of stereoscopic vision and all that it entailed in the stimulation of brain-growth, which ultimately culminated in the emergence of human powers of foresight and discrimination (see Presidential Address to the Anthropological Section of the British Association, 1912).

Fossil Remains of Extinct Members of the Human Family.—

The conclusion to which the study of man's ancestry has led investigators, that the brain led the way in the emergence of human characters, received a dramatic confirmation in 1912, when the late Mr. Charles Dawson and Dr. Smith Woodward announced that the former had discovered (in a patch of gravel alongside the path leading to Barkham Manor, the residence of Mr. Charles Kenward, near Piltdown in Sussex) fossilized fragments of the skull of a palaearctic member of the human family quite unlike anything known hitherto (C. Dawson and A. Smith Woodward, "On the Discovery of a Palaearctic Skull and Mandible in a Flint-bearing Gravel overlying the Wealden (Hastings Beds) at Piltdown, Fletching (Sussex)," Quarterly Journal of the Geological Society, vol. Ixx. (1913) and vol. Ixx. (1914); the best photographs of these highly significant specimens will be found in A Guide to the Fossil Remains of Man in the Department of Geology and Palaeontology in the British Museum, written by Dr. Smith Woodward, as Dr. Smith Woodward has called him, had a brain which fell between (as it were, in the case is concerned) of variation of modern man's brains. But it displayed some remarkable deficiencies, more especially in the singularly poor development of those frontal, parietal and temporal areas, the noteworthy expansion of which is the fundamental distinctive character of the human brain. Perhaps the most interesting feature of the endocranial cast of the Piltdown man is the remarkable localized overgrowth of that particular part of the brain (the posterior part of the superior temporal convolution) which in modern man is intimately associated with the appreciation of the aesthetic symbolism of speech. As a somewhat analogous host is found on the endocranial cast of Pithecanthropus, the fossilized remains of which were found nearly thirty years ago in Java by Dr. Eugén Dubois, it affords grounds for the view that the acquisition of speech may have been one of the essential elements in the transformation of an ape into a man.

It is of fundamental importance to realize that, in spite of its size, the endocranial cast of Eoanthropus reveals these indubitable traits of an extremely early phase in the attainment of human characters; and the brain was contained in a skull of a peculiarly distinctive type. For so similar is the form of the jaw that many anatomists and palaeontologists refuse to admit that it is human, and claim that a hitherto unknown chimpanzee expired at Piltdown in Pleistocene times on the same spot as Eoanthropus and that the former left its jaw and the latter its skull. This view is widely held, but chiefly by non-British anatomists (see, for example, M. Ramström, "Der Piltdown Fund," Geol. Inst. of Upsala, vol. xvi., 1910) who have never studied the actual fossils. Had they done so they would have realized that, in spite of its form, both the mandible itself and the teeth lodged in it display undoubted human characters. Moreover the cranium also reveals much more primitive features than is commonly supposed by those who have not seen and handled it. In fact there is no reason for withholding assent to the view that this remarkable cranium, which formerly lodged a brain of extremely primitive character, once formed part of the same individual whose jaw had not yet lost all the marks of the ape.

A vast amount of writing has accumulated since 1912 with reference to this remarkable skull, but most of this literature is irrelevant and misleading; as the authors have not seen the material about which they write and have no adequate realization of the true state of affairs.

As to the age of the Piltdown skull, precise information is lacking. It was found in an ancient river bed along with rolled teeth of Pliocene elephants and rhinoceros that had been washed out of some older geological formation, and unrolled teeth of early Pleistocene hippopotamuses and beaver and the base of the antler of a red deer. From a consideration of all the evidence it
is reasonable to assume that the Pitrdown man lived in the early Pleistocene period, and this inference is borne out by the crude implements of flint and elephant-bone found along with the skull. The crucial importance of *Eoanthropus* depends upon the fact that it is so obviously close to the main line of descent of modern man. Yet it reveals such astounding resemblances that many—perhaps the majority of—recent writers want to claim its jaw as a chimpanzee’s. This in itself is a striking demonstration of the closeness of the affinity of primitive man and certain apes.

Although in 1921 it was nearly thirty years since Professor Eugen Dubois discovered at Trinil, on the banks of the Solo river in Java, the fossil which he regards as parts of one individual, *Pithecanthropus erectus*, his monograph on the subject had not been published. Nevertheless the stream of writings on this ape-man was still flowing unabated. In Boule’s *Les Hommes Fossiles* (1921) the distinguished French palaeontologist still maintained that *Pithecanthropus* is not a member of the human family, but is an ape. Dubois himself maintains that it is neither a man nor an ape, but a creature really intermediate between them. But the endocranial cast of *Pithecanthropus* reveals the fact quite definitely and surely that as regards its size, shape and the relative proportion of parts, this so-called ape-man of Java comes within the range of the *Hominidae*. Moreover, as has already been mentioned, its endocranial cast exhibits a fullness of the postero-superior part of the temporal area which suggests the acquisition of the charactristics by human powers of speech. The question is still debated whether the thigh-bone found in the same bed as the skull-cap of *Pithecanthropus* really belonged to the same individual. It is so obtrusively human that some authorities find a difficulty in associating it with the skull: but the balance of evidence is in favour of both being parts of one individual, the most primitive and the earliest known member of the human family, aberrant both in physical type and habitat. Controversy was still proceeding in 1921 as to the age of the *Pithecanthropus* remains, and new evidence provided by the Selenka expedition has been used to strengthen the hands of those who object to the claim of Dubois of the remains belong to the Upper Pliocene and maintain that these earliest known representatives of the human family are to be referred definitely to the commencement of the Pleistocene period (Selenka and Blanckenhorn, “Die Pithecanthropus-Schichten auf Java,” *Geologische und palaeontologische Ergebnisse der Trinil-Expedition, Leipzig*, 1911).

In 1905 the remains of *Pithecanthropus* represented the only known member of the family *Hominidae* which did not belong to the genus *Homo*. Since then, however, the remains of other forms have been revealed that surely deserve generic distinction. In 1900 a fragmentary jaw came from an abraded and burned skeleton in the Krapina cave near Krizevci, which was described by Schoetensack as a hitherto unknown member of the human family which he called *Homo heidelbergensis*. But its age and peculiar features remove it so far from all the members of the genus *Homo* that it is more in accordance with the proper perspective to follow Bonarelli who has created for its reception the genus *Paloanthropus*. It is extremely massive and is unlike any other human jaw, not merely by reason of its size but also in the ape-like recession of its chin.

**Modern Man**—The fossilized remains of part of a cranium and some long bones found in 1856 by some workmen in the Feldhofer Grotto in the Neanderthal Valley (between Elberfeld and Düsseldorf in Rhenish Prussia) are now generally admitted to represent a species of the genus *Homo* that is definitely differentiated from the species *sapiens*, to which all the living races of man belong. This extinct species is known as *H. neanderthalensis*, a name first suggested in 1864 by Prof. King of Galway. In 1848 a fossil skull was found at Gibraltar by Lt. Flint, but no attention was devoted to it until Busk described it in 1864; and it is now commonly supposed to be a female of the *Neanderthalia* group of the Lower Quaternary (1909) considers it to be more primitive and earlier than the true Neanderthal peoples. Other examples of the Neanderthal species have been found in the grotto of Spy (Belgium) in 1866, at Krapina (Croatia) in 1899, at La Chapelle-aux-Saints (La Corrèze, France) in 1908, Le Mouster in the Dordogne (1909) and in the same year at La Ferrassie in the same region. Another skull was found in the same region in 1910, and in 1911 yet another at Le Quesnoy (Charente). To this remarkable set of skeletons found in France, which give us so complete a picture of the distinctive features of this brutal extinct species of our genus, is to be added fragments of two jaws found in 1914 at Ehringsdorf near Weimar in Germany (see Hans Virchow, *Die menschlichen Skeletreste aus dem Kämpfischen Bruch im Travertin von Ehringsdorf bei Weimar*, Jena, 1920). The vast literature that has accumulated with reference to the other examples of *Homo neanderthalensis* will be found summarized in M. Boule’s *Les Hommes Fossiles* (Paris, 1921) as well as in H. F. Osborn’s *Men of the Old Stone Age* (New York, 1913) and W. J. Solias’ *Ancient Hauers and their Modern Representatives* (London, 2nd ed. 1914).

Neanderthal man is now revealed as an uncouth race with an enormous flattened head, very prominent eye-brow ridges and a coarse face. The trunk is short and thick, the robust limbs are short and thick-set: the broad and stooping shoulders lead by a curve to the forwardly projected head set on an abnormally thick neck. The hands are large and coarse and lack the delicate play between thumb and fingers which is found in *Homo sapiens*. The large brain is singularly defective in the frontal region. It is clear that Neanderthal man’s limbs and brain were incapable of performing those delicately skilled movements that are the distinct prerogative of *H. sapiens* and the chief means whereby the latter has learned by experiment to understand the world around him, and to acquire the high powers of discrimination that enabled him to compete successfully with the brutal strength of the Neanderthal species.

The Neanderthal race of men, with their distinctive Mousterian culture, suddenly disappeared from Europe, and were replaced by immigrants belonging to our own species, who brought with them to Europe the germs of the phase of culture known as Aurignacian. These newcomers were members of the Cro-Magnon race, a very tall people with large dolichocephalic skulls and relatively broad face. They probably entered Europe from the S., because their settlements are found chiefly near the Mediterranean coastline, in northern Africa, Sicily, Italy, southern France and Spain. The coming of this superior race of highly intelligent men is revealed also by the sudden improvement in the technique of the stone-work and the appearance, especially in the caves of southern France, of mural paintings revealing new powers of artistic observation and skill in depicting the animals which these people hunted. There is revealed also in the Cranial and the Germs of the art of our own race. At a later period the members of another race (also dolichocephalic, but with much narrower and more harmonious face than the Cro-Magnon people) began to make their way into Europe from the East, probably by way of Poland and Moravia, Hungary and Bavaria, thence into France. These people are often known as the Brünna race and their culture as Solutrian. The skeletons are found deeply imbedded in loess along with the bones of the woolly mammoth, woolly rhinoceros, giant deer, reindeer, etc. Their culture is distinguished by the splendid skill in flint-polishing imparted to their implements. Although it lasted only a short time in Europe and never extended as far as Spain or the Mediterranean area, this method of stone-working spread far and wide, to Egypt, Australia and America, and in the latter two countries persisted until the present time.

After the Solutrian came the Magdalenian phase of culture, which marked the culmination of the skill and achievement of man before agriculture. This new development was not derived from the Solutrian art, but was brought into Europe and replaced the latter. It lacked the superb skill of the Solutrian flint-workers, but was characterized by a high degree of ability in painting and sculpture.

**For information concerning the culture of the Magdalenian epoch in France and Spain see Osborn’s *Men of the Old Stone Age*; also the**

The Magdalenian phase of culture in western Europe was succeeded by the Neolithic, a momentous event, which was heralded by the arrival in different parts of Europe of a variety of races: (a) an advance wave of the Mediterranean race which was soon to introduce the distinctive elements of the Neolithic culture, but at first introduced the Azilian-Tardenoisian industry into Spain and France; (b) another offshoot of the Mediterranean race that made its way to Bosten in Eastern Bavaria; (c) a race possibly of Nordic affinities that appeared on the coasts of the Baltic, but is known only by the Maglemose industry; and (d) a broad-headed advance guard of the so-called Alpine or Armenoid race (distinguished as Furfooz-Grenelle) found along with the dolichocephalic people at Bosten and also in Belgium.

The coming of the Neolithic people into western Europe marks the advent there of people who brought the rudiments of the great world civilization that was being built up in the Ancient East. For the cultivation of barley and wheat, the making of pottery, the weaving of linen and several other distinctive features of the Neolithic phase of culture are clearly instances of customs which had their origin in Egypt or its neighbourhood at a time when western Europe was still in the so-called "Upper Palaeolithic" phase. Towards the end of the Neolithic phase in the W., when megalithic monuments make their appearance in the Pyrenees, the stone Age people of the Near East had already penetrated to Egypt ("The Evolution of the Rock-Cut Tomb and the Dolmen," *Essays and Studies presented to William Ridgeway, 1913*), we get even more definite indications of the source and date of the cultural inspiration to build such peculiar and distinctive structures; and the close identity of their geographical distribution with those of the ancient exploitation of flint, gold, copper, tin, pearls, jet, amber and purple indicates clearly enough the motives that attracted the culture-bearers to certain localities and made them foci of new developments of culture (W. J. Perry). It is important to remember that in the home of their invention the working of gold and copper preceded the building of stone monuments by some centuries; but as prospectors searched for gold and copper ores they invaded territories and obtained these materials from them long before the metals themselves were worked or used locally, i.e. while the latter still remained in the stone phase of culture.

These are very cogent reasons for the belief that the working of copper first began in Upper Egypt or Nubia (Relsner, quoted by Elliot Smith, *The Ancient Egyptians*, chap. ; see also *Man*, Feb. 1916, p. 26) and from there spread to Palestine and Syria, to Elam and Asia Minor, Cyprus and the Aegean Islands, and it is probable that the making of bronze was first devised early in the third millennium in the neighbourhood of the south-eastern corner of the Caspian, perhaps near Meshed, and from there the practice spread W. and S., and later E., until not only western Asia and Europe passed into a Bronze Age, but also eastern Asia and Central and South America.

The Talgai and Wadjak Skulls.—At the meeting of the British Association in Sydney in 1914 Prof. J. T. Wilson and T. W. Edgeworth David exhibited the fossilized skull of a boy of about fifteen years of age, which had been picked up thirty years before in Queensland. A full account of this skull was published in 1918 (Steward Smith, "The Fossil Human Skull found at Talgai, Queensland," *Philosophical Transactions of the Royal Society, B*, vol. cccviii.). The interest of this earliest Australian skull lies in the fact that it conforms so closely to the type of the existing aboriginal Australian, its only peculiarity being the exceptional size of the palate and teeth, and especially of the large and salient canine teeth. The discovery of fossilized dog’s teeth in the cave breccias of New South Wales and Victoria go to prove that early man accompanied by his dogs must have ferried across Wallace’s line to make his way into New Guinea and Australia.

The publication of the account of this proto-Australian skull stimulated Prof. Eugen Dubois to announce the information that thirty years earlier he had found fossilized remains of members of the same race at Wadjak in Java ("De proto-Australische fossiele Mensch van Wadjak, Java," *Koninklike Akademie van Wetenschappen te Amsterdam, Deel, xxix., May 7, 1919*).

Boskop Skull.—About the same time that the discovery of the Talgai skull was announced in Australia the discovery was recorded of a very different type of fossilized skull from Boskop in the Transvaal (S. H. Haughton, "Preliminary Note on the Ancient Skull Remains from the Transvaal," *Transactions of the Royal Society of South Africa*, vol. vi., 1917). The fossils consist of part of the brain case and jaw of a type of man differing profoundly from the earliest known inhabitants of S. Africa, the Bushman and the Hottentot. They represent the remains of a variety of *Homo sapiens* in some respects akin to the Cro-Magnon race, the earliest type of *Homo sapiens* known in Europe.

Oldowan Skull.—In 1914 also the fossilized remains of a human skeleton were found in Central Africa (H. Reck, "Erste vorlängige Mitteilung über den Fund eines fossilen Menschenknochens aus Zentralafrikal", *Sitzungsberichte der Gesellschaft naturforschender Freunde zu Berlin*, 1914), but adequate information concerning this discovery is still lacking.

Early Man in America.—Although it is certain that at a relatively early period in the history of *Homo sapiens* there must have been an immigration (by the Bering Strait route into N.W. America) of people sprung mainly from the proto-Mongolian stock, living E. of the island-waters of the Pacific river, no remains of really early man in America have yet been discovered. The mere finding of implements of Palaeolithic types proves little, because the making of such implements has survived in the East, and the art may have been carried to America within relatively recent times. Up to 1921, the most recent discovery of human remains supposed to be early was made at Vero in Florida in 1916, but the geological evidence showed that the fossilization had occurred in post-Pleistocene times. There is, however, still great uncertainty as to the age of these remains, which do not differ in type from many modern American Indians.

The whole problem of early man in America has been explored in a severely critical spirit by Dr. Ales Hrdlicka, who gives a full bibliography ("Skeletal Remains suggesting or attributed to Early Man in the Americas," *Smithsonian Institution, Annual Miscellaneous Publications, vol. 33*, Washington, 1907; "Early Man in S. America," *ibid., 1912; and "Recent Discoveries attributed to Early Man in America," *ibid., 1918*).

It is probable that the substratum of the early population of America consisted of a colony of a proto-Mongolian race mixed perhaps to some extent with proto-Armenoid elements in the original Siberian homeland. In later ages, more especially between about 300 B.C. and 1000 A.D., this population has been very considerably diluted—more especially on the Pacific coast—by a steady percolation of a variety of alien elements into the N.W. coast from Asia and into Central and South America from Polynesia and Micronesia in numbers sufficient materially to affect the physical type of the people of the western litoral and differentiate them from the eastern people.

For the evidence in support of this (but with a different interpretation) see Clark Wissler, *The American Indian* (New York, 1917). Dr. Wissler’s book is also an invaluable summary of the present state of our knowledge of the geographical distribution of the arts and crafts of America, and a striking demonstration of the fact that the arts of agriculture, pottery, weaving, stone-working, metalurgy, etc., were diffused abroad in America from one centre somewhere in the region of Honduras. But he stoutly denies the conclusion (which is clearly drawn from the evidence presented) that the elements of this exotic culture were planted in Central America by small groups of immigrants who had crossed the Pacific Ocean via Polynesia from Cambodia and Indonesia.

Classification of Existing Races.—Between 1910-20 it became increasingly clear that the generally adopted classification of mankind and of early culture was unsatisfactory, and not in full accordance with the facts that are now available. In the introduction of the terms "Palaeolithic" and "Neolithic" by Sir
John Lubbock (afterwards Lord Avebury) served a useful purpose for a time in discriminating between the early and the later methods of flint-working before the discovery of bronze. But it is now known that the great break in the technique of stone-working did not occur at the transition from the Palaeolithic to the Neolithic phase, but when the so-called 'Upper Palaeolithic' gave place to the so-called 'Lower Palaeolithic.'

The vast significance of this great revolution in man's history (at any rate in western Europe) is emphasized by the fact that it coincided with the final disappearance of the species H. neanderthalensis and the coming of the members of the species to which we ourselves (and all existing members of the human family) belong, i.e. H. sapiens. The replacement of the degraded type of mankind with his crude Mousterian culture and the coming of H. sapiens with his greater skill and artistic aptitude is surely the most significant revolution in the whole of man's history. To discriminate between the two cultures, Elliot Smith has suggested the terms, 'palaeanthropic' and 'neoeanthropic' to apply respectively to the extinct species and their works and H. sapiens and his achievements ('Primitive Man,' Proceedings of the British Academy, 1917).

All the races of man that exist at present belong to the species sapiens, but they differ profoundly in type and in the probable dates of their differentiation the one from the other. The most primitive race of all is the aboriginal Australian, who represents the survival of the earliest phase of H. sapiens with relatively slight change. After he separated from the rest of mankind he found himself in regions where the Pleistocene fauna and flora had disappeared, and the proto-aboriginal people called pre-Davidian. The rest of this race wandered E. until they reached Australia, small remnants remaining in some of the Indonesian Is. as abiding witnesses of the ancient migration. Probably at a much later period the Negro and Negrito became differentiated from the rest of mankind and found their area of characterization in tropical Africa, from which place in later times negroid peoples drifted along the whole southern littoral of Asia to Indonesia and Melanesia. It is probable that the Bushmen and Hottentot races represent early differentiations from the Negro stock. These two races, Australian and Negro, retain the black colour of skin which originally was probably common to all mankind and his nearest relatives, the gorilla and chimpanzee. After the Australian and Negro had been differentiated the rest of the human family attained a higher plane of development associated with a bleaching of the skin, a refinement of the features and a further growth and specialization of the brain. This pale-faced stock became broken up during the glacial period into four main stocks which became isolated the one from the other. Probably the earliest to wander off and become segregated—possibly in the region of the Yellow river—was the proto-Mongoloid group which in course of time became specialized in structure as the Mongolian race. The next group probably found its area of characterization in N.E. Africa where it assumed the less specialized, i.e. relatively primitive, features that distinguished the Brown or Mediterranean race. Two other groups became isolated in the N.—one, probably in Turkestan, assumed brachycephalic traits and developed into the so-called Alpine or Armenoid race; the other, somewhere to the N.W., retained its primitive dolichocephaly but developed the distinctively blond traits that are the obtrusive characteristic of the Nordic race. Within each of the areas of characterization groups became isolated and differentiated in greater or less degree the one from the other. Moreover at the end of the glacial period, when the great ice-barriers disappeared there was extensive mingling not merely of the formerly isolated groups of the same race, but also of different races. In Siberia especially there was a complex intermixture of Armenoid, Mongolian and Nordic peoples; and in western Asia and the Mediterranean littoral a variety of blends of Brown and Armenoid peoples. It was probably after a certain amount of such intermixture occurred near the head-waters of the Yenisei that an essentially proto-Mongolian people moved E. and crossed into America as the first inhabitants of the New World.

The whole racial problem was in 1921 still in process of reconsideration. The best collection of facts relating to the subject will be found in the new edition of Keane's Man, Past and Present, edited by Quiggin and Haddon (Cambridge, 1920), but the headings of the chapters preserve the fallacies of the extant system of classification that is now being discarded.

Only the most inveterate prejudice can blind one to the fact that the widespread movement of small groups of people Polynesia (the chief ingredients of whose civilization were contributions of the Brown and Armenoid races) served to link up America with the Old World, and to provide the means whereby the elements of the early civilization of south-eastern Asia were introduced into Central America and Peru. No ethnologist doubts for a moment that the early mariners reached Easter I., because the island is peopled, and the language and the culture of the islanders afford proof of the fact that they came from the West. But it must be apparent that for every ship that chanced to strike that microscopic islet in eastern Polynesia there must have been hundreds, if not thousands, that missed it and were swept on to the coast of America. The whole culture of this Pacific littoral affords corroboration of evidence of the fact that these early mariners did plant in Central America and Peru the beliefs and customs which we know them to have had.

Mr. Charles Hedley claims (Man, Jan. 1917, p. 12) that the peoples of Oceania obtained from America the coconut and the sweet-potato as the result of such intercourse. The recent discovery (Chinnery) of the use of tobacco in the central highlands of New Guinea raises the question whether America learned the use of tobacco from Papoa or the reverse. The very primitive and peculiar methods of smoking tobacco that Lt. Chinnery discovered in New Guinea suggest that if introduced from the East it must have occurred at a relatively remote period.

The Diffusion of Culture.—For half a century ethnology has been suffering from a grave reaction which it is only now beginning to overcome. Thus in the earlier article it was stated (see 2.119):—

"Anthropological researches undertaken all over the globe have shown the necessity of abandoning the old theory that a similarity of customs and superstitions, of arts and crafts, justifies the assumption of a remote relationship, if not an identity of origin, between races. It is now certain that there has ever been an inherent tendency in man, allowing for difference of climate and material surroundings, to develop culture by the same stages and in the same way. American man, for example, need not necessarily owe the minutest portion of his mental, religious, social or industrial development to remote contact with the aborigines of Europe or Asia. His adherence to certain superstitions is no reason to suppose identical usages. An example in point is that of pyramid-building. No ethnical relationship can ever have existed between the Aztecs and the Egyptians; yet each race developed the idea of the pyramid-shaped tomb through the 'Mansfield' theory that psychological similarity which is as much a characteristic of the species man as is his physique."

This once authoritative statement is cited at length to call attention to the actual teaching in ethnology which went far to sterilize half a century's intensive investigation; and as the present tendency is to sweep away all such sophistry and introduce into ethnology the real scientific method, it will be useful to examine the claims of the system which has to be got rid of. Let us take the above five sentences as quoted seriatim. As it stands the first sentence would be altogether satisfactory if it really meant that ethnology utterly and totally abandoned the view that similarity of customs implied racial kinship. The fact that a Japanese makes a steam-engine does not transform him into an Englishman! But as the second sentence shows, the ethnologists were confusing race and culture. The Japanese engineer who builds the steam-engine does not do so because there is "an inherent tendency in man to develop culture in the same way": the fact that the making of a steam-engine does not transform him into an Englishman does not preclude the recognition of the debt he owes directly or indirectly to Englishmen for the idea and for the methods of putting it into practice. The Japanese notion of "the inherent tendency in man" (in other words what the psychologist calls an instinct) to build steam-engines or pyramids, both the facts of history and the principles of psychology teach us that there
is no such specialized instinct. With reference to the protest that American man did not borrow mental, religious, social and industrial ideas from Asia, no one has provided more cogent illustrations of the fact that he did do so than the author of the disclaimer himself (see, for example, "On the Diffusion of Mythical Beliefs as Evidence in the History of Culture," Report British Association, 1894, p. 774; "On the Game of Puluott," Journal Anthropological Institute, vol. viii., 1879, p. 128). The series of step-pyramids that are scattered from Mesopotamia to Ceylon, to Cambodia and Java, to Japan and Shantung, to Tahiti and the Marquesas, to Peru and Mexico afford so striking a demonstration, not only of the spread of a very definite and peculiar phase of culture, but also of the route of the diffusion that many of the reactionary school in ethnology have felt it incumbent on them to get rid of evidence that was so awkward and obstructive.

It was formerly claimed in effect that man had been a nest-building instinct, which presumably was kept in check by the vast majority of mankind, but burst its bounds in a chronological sequence among the peoples scattered along the coasts from Egypt to Central America. The more fully the details of these pyramids are studied the more complete is the demonstration of their derivation one from the other as the stream of culture moved from West to East. In Ceylon at Polonnaruwa we find pyramids of Mesopotamian design but built of stone like those of the Egyptians. The less ornate Khmer pyramids, such as Ka-Keo and Ba-Kong, of Cambodia, reproduce the Sinhalenese models with singular accuracy; and then pyramids of the same type appear in Queensland, Peru and Equador, Central America and Mexico, the Mississippi Valley and the south-eastern region of the United States, the transference of the incentive across the Pacific having been effected probably between the third and the tenth centuries A.D.

The acceptance of ideas concerning the possibility of spontaneous generation—with curious lack of knowledge and logic the ethnologists called it "evolution"—of similar ideas and customs among widely distant peoples was paralyzing the study of ethnology and removing it farther and farther from the stimulating influence of serious discussion and honest observation. Dr. W. H. H. Rivers was mainly responsible for leading ethnology out of this morass. In his presidential address to the Anthropological Section of the British Association in 1911 he exposed the fallacies of the popular ethnological doctrine and insisted on the importance of the diffusion of culture. One of the fallacies that had led ethnologists astray and facilitated the acceptance of the weird speculation of spontaneous generation of culture was the belief that useful arts could not be lost. One finds this view expressed in the earlier article (see 2.117):—

"Had the Australians or New Zealanders, for instance, ever possessed the potter's art, they could hardly have forgotten it." By demonstrating the fallacy of this argument and showing that even so vital an art as boat-building could be lost by an island people, Dr. Rivers (Report British Association, 1912, p. 598; also Festschrift Tillmann Edward Westermack, Helsingors, 1912, p. 100) removed the only serious obstacle in the way of the acceptance of the truth of the diffusion of knowledge in the way we know it to have been spread abroad in historical times.

From a detailed study of the technique of embalming Elliot Smith became convinced that the evidence provided by mummies from the islands in Torres Strait was so conclusive a proof of the influence of Egypt as to leave no possibility of doubt as to the certainty of the spread of culture from Egypt to New Guinea and Australia; and as the result of an examination of methods of mumification in various parts of the world he put forward a theory of The Migration of Early Culture (Manchester, 1913), in which the evidence provided by the geographical distribution of megalithic monuments, sun-worship, ear-piercing, tattooing, couvade, artificial deformation of the head, the use of the swastika, etc., was used to corroborate the reality of the diffusion of the ingredients of early civilization. If, as this theory claimed, the spread of culture took place by a large measure by sea ("Ancient Mariners," Journal of the Manchester Geographical Society, 1917), the Indonesian archipelago ought to preserve some evidence of the movement by which the custom of building stone monuments reached Oceania from the West. This evidence was revealed by Mr. W. J. Perry (The Megalithic Culture of Indonesia, Manchester, 1918), who rendered an even greater service by explaining the motives of the wandering peoples who were mainly responsible for distributing abroad throughout the world the germs of civilization. Men, prosing for gold, copper, silver, tin and other metals, or for flint, turquoise, lapis lazuli, amber or jet, or divers searching for pearls or pearl-shell were the means of planting the elements of culture in outlying places in the world and making them foci of civilization ("The Relationship of the Geographical Distribution of Megalithic Monuments and Ancient Mines," Mem. and Proc. Manchester Lit. and Phil. Soc., 1915; "The Geographical Distribution of Terraced Cultivation and Irrigation," ibid., 1916; "An Ethnological Study of Warfare," ibid., 1917; "War and Civilization," Bull. John Rylands Library, vol. iv., 1918).

Since Perry put forward this illuminating suggestion its truth has been repeatedly confirmed by investigations in the British Is., in the Caucasus, in Hyderabad, in Siberia, in eastern Asia, in New Guinea and Oceania, and especially in America. Working out the details of the geographical distribution of the different ingredients of civilization one is now able to reconstruct the past history of the beginning of culture and its diffusion throughout the world. We now realize that the incentive that spurred men on to build up the artificial structure of civilization was primarily the instinct of self-preservation. The realization of the dangers to life impelled men to seek for materials which they believed to be life-saving or death-avoiding. This was the original value attached to pearls and gold, to incense and jade, and to most of the things which the earliest members of our species sought for in the belief that no adventure was too hazardous and no danger or difficulty too great if by overcoming it they could secure the elixir of life (Elliot Smith, The Evolution of the Dragon, Manchester, 1910).

The Beginning of Agriculture.—If one single event more than another can be regarded as the foundation of civilization it is surely the invention of agriculture. Much speculation has been made as to where and how this crucial event was brought about; but the breeding experiments of such investigators as Prof. Biffin of Cambridge and the late Mr. Aaronsohn (see Coulter, Fundamentals of Plant Breeding, 1914, p. 102) dispose once for all of the popular view that primitive man more than sixty centuries ago produced the barley and wheat, which has been the staple foods of a large section of mankind since then, by an elaborate and long-continued process of experimental breeding. Having disposed of this anachronism, one is in a better position to appreciate the cogency and conclusiveness of the claim set up recently by Prof. Thomas Cherry of Manchester ("The Discovery of Agriculture," Proceedings of the Australian Association for the Advancement of Science, 1921), that the Nile valley was the place where barley was found growing in a natural state, and that agriculture associated with basin irrigation was invented simply by imitating the natural conditions which the proto-Egyptians had constantly before their eyes. Dr. Cherry has pointed out that in Egypt alone the climatic and seasonal conditions are favourable for the natural growth of barley; and we know that it was the staple diet of the earliest Egyptians (G. Elliot Smith, The Ancient Egyptians, 1911, p. 41). The climatic conditions in Mesopotamia, Syria, and Asia Minor are such that the cultivation of barley became possible there only when men applied the lessons of artificial irrigation which they had acquired in Egypt. Dr. Cherry believes that wheat must have grown naturally on some of the smaller Aegean islands—he mentioned Melos and Naxos—and was first cultivated centuries after barley and by men who had learned the art of agriculture directly or indirectly from Egypt. But before the close of the fourth millennium the Egyptian technique of agriculture and irrigation had been adopted in Sumer and Crete and probably also in Syria and Asia Minor. Soon afterwards it was to spread N. and E. to Turkestan and Baluchistan.
and in the W. to Europe, as one of the distinctive features of the Neolithic Age there.

The effect of the discovery of a means of securing a certain food supply capable of being stored for use in the lean periods of the year not only led, for the first time in the world's history, to a settled community and a steady increase in population within the settlement, but in addition it gave men leisure to think of other things than the mere struggle for existence. It is no small chance circumstance that the invention of agriculture is intimately related to the development of the potter's art, to the building of more pretentious houses, to the weaving of linen and the domestication of milk-giving cattle. But it also provided the predisposing circumstances that compelled the organization of labour and the assumption of control of his fellow men by a leader who became a king, and brought about the curious result that the chief function of this earliest ruler was to be the irrigation engineer to the community, as we know to have been the case both in Egypt and Sumer. As this settled community in the Nile valley increased in number, the carpenter was forced upon it of making more ample provision for disposing of its dead; and out of the circumstances that attended these events there came into existence the arts of the embalmer, the carpenter and the stonemason. Architecture had its birth in the proto-Egyptian necropolis. Ship-building also was invented in close association with this train of events: and the first great maritime expeditions of which any hint has survived had for their object the obtaining of materials needed by the embalmer and the tomb-builder. Probably in the fourth millennium sea-going ships were already confining to Syria Asial and Crete, to southern Arabia and E. Africa (Elliot Smith, "Ancient Mariners," Journal of the Manchester Geographical Society, 1917).

The Beginning of Civilization.—After many years of fluctuating diversities of opinion it is now widely admitted that there is a very close genetic relationship between the earliest civilizations of Egypt and Babylonia. The identity of their burial customs, their methods of agriculture and irrigation, the use of bricks, cylinder seals and mace-heads, the use of copper and painted pottery, the weaving of linen and the choice and methods of preparing cosmetics, and above all their beliefs and religious practices—these and scores of other customs reveal the fact that the cultures of the earliest peoples of Egypt, Sumer and Elam were derived from a common source. The recent incident that compelled scholars frankly to admit the reality of the cultural link between Egypt and Babylonia in very early times was the acquisition by the Louvre of a predynastic flint-knife with a handle carved from the tooth of a hippopotamus which is said to have come from Gebel el-Arak near Nag'Hamadi in Upper Egypt (Bénédicte, "Le couteau de Gebel el-Arak," Fouillons d'Egypte Prot., Mon. et Mém., xxvi., i., 1916). The design engraved on the handle is claimed to be very un-Egyptian and to afford certain evidence of cultural contact with Sumer. But many scholars now claim that Egypt obtained the elements of her civilization from Sumer (see, for example, Prof. S. Langdon, "Early Chronology of Sumer and Egypt," Nature, May 5 1921, p. 313). In support of this contention Prof. Langdon claims that "recently discovered dynastic tablets establish the date of the earliest kings of Mesopotamia as early as 3000 B.C." whereas he attempts to fix the beginning of the first Egyptian dynasty by comparing the methods of year-dating of the famous Narum-Sin (2750–2730 B.C.) with those of Egypt, arguing that Naram-Sin borrowed his system of year-dating from Egypt and was contemporaneous with the last two kings of the second Egyptian dynasty. He claims to have confirmed the date circa 3200 B.C. for Menes. But a wholly unexpected revision of Egyptian dating has come from the German school of archaeology which was responsible for the minimal date 3200 B.C. which Prof. Langdon claims to have established by independent evidence.

Prof. L. Borchardt has recently set forth at length a series of arguments, mainly based on astronomical data, to prove that the first Egyptian dynasty began in 4186 B.C. and that the sixth dynasty lasted from 2920 to 2750 B.C. (Die Annalen und die Festlegung des Alten Reiches der ägyptischen Geschichte, Berlin, 1919). This new estimate, even if it should prove to be true, would not necessarily be fatal to Langdon's claims. But there are reasons of other kinds that demonstrate the derivation of Sumerian and Elamite culture from Egypt.

If it can be shown that Egypt was the home of the invention of agriculture, of irrigation, of the working of gold and copper, of the weaving of linen and the making of bricks, of the building of sea-going ships and the use of incense it necessarily follows that Sumer and Elam must have acquired these practices from Egypt, especially as Prof. Langdon rightly claims that the spread of culture took place mainly by sea-routes. As neither the Sumerians nor the Elamites are known to have built sea-going ships nor to have had any motives for doing so, one naturally assumes that the Egyptians (as the builders of the earliest known sea-going ships) took the initiative in opening up the communication by sea with the Persian Gulf, as we know they did early on with the coasts of Palestine, Syria and the Caspian Sea. But the facts brought to light by the French excavations in Elam seem to prove quite conclusively that the predynastic civilization of Egypt was planted there, probably by miners working the copper ore.

Perhaps the most valuable evidence bearing on the early inter-relationships of Egypt, Elam and Sumer and the wider spread of their cultural influence is afforded by the important study of early painted pottery, which M. Edmond Pottier contributed to the valuable series of reports of M. de Morgan's Délivrance en Perse ("Etude Historique et Chronologique sur les Vases Peints de l'Acropole de Suse," Mémores de la délégation en Perse, Tome XIII. "Recherches Archéologiques," 5ème Série, 1912, p. 27). According to him Susian ceramic ware is revealed as the product of a very primitive civilization; but in addition it recalls (or perhaps it would be more correct to say, reveals the germ of) certain highly perfected industries such as that of the Greeks. It is, in fact, an amazing mixture of inexperience and skill—the sort of result one might expect to find when an industry which has been developed elsewhere is suddenly transplanted to a new country, and work requiring special skill is unceremoniously entrusted to the incompetent hands of local artisans. The Susian workmanship in fact displays clearly the fact of the derivation of the ceramic craft from elsewhere.

In the lowermost level in which there is any evidence of human occupation at Susa, pottery was found in association with copper and stone weapons. This suggests, according to Pottier (p. 60), that the pottery is Eneolithic and that the first colonization of Susa took place in the Eneolithic epoch. For in this lowest level the evidence of the arts and crafts indicates that a fully-developed civilization was present from the beginning of the Susian record preserved for us to study. Linen, for example, was found along with the weapons—an association with copper and painted pottery which further strengthens the proof of the Egyptian origin of the imported Susian civilization. Necklaces of lapis lazuli and turquoise afford evidence, according to Pottier (p. 61), of foreign relations. They suggest, in fact, the possibility of connexion with the regions around the southern end of the Caspian (13 and 14) where these stones are found and were worked in very early times.

Discussing the date of these earliest Susian remains M. Pottier (p. 63) thinks that they are slightly earlier than any of the known Sumerian objects: but he is not inclined to accord them an age many centuries earlier than the time of Ur Nina of Lagash (2800 B.C.). It seems quite clear that there are no valid reasons for attributing to any Elamite or Sumerian remains a date earlier, if indeed as early, as that of the First Egyptian Dynasty. Now the proto-Egyptians had been working copper, making linen and painting pottery, for many centuries before this earliest possible date for the commencement of Elamite and Sumerian civilization. Hence, as undoubtedly borrowing did occur, it is clear that Elam and Sumer acquired the germs of their civilization directly or indirectly from Egypt, or from the same source as Egypt.
M. Pottier does not go so far as to make this claim, but he submits all the evidence that makes its adoption unavoidable:

"En examinant les monuments égyptiens de l'âge préhistorique et des premières dynasties, tout le monde sera frappé des traits de ressemblance nombreux qu'ils présentent avec les trouvailles élamites des couches les plus anciennes. . . . (En Egypte) on retrouve des formes, des sujets, des détails de technique qui évoquent aussi le souvenir des antiquités de Suse: vases de pierre dure et d'albérite" (p. 82).

M. Pottier discusses the problem in its wider bearings (pp. 83–83), and elsewhere (pp. 67 et seq.) sets forth his views on the psychology of originality in invention and of the significance and the manner of cultural diffusion. Thenceforth he concludes that Suse had not at all been colonized as far as Baluchistan, and probably India, in the east.

In Armenia and the Caucasus painted Susian-like vases do occur, but only very rarely (Pottier, p. 73).

"Cette poterie du Caucase, dont la date n'est déterminée, est sans contredit affiliée par la tradition à la fabrique élamite" (p. 74).

In Galatia and Cappadocia painted pottery of the same type is found, which is certainly not of Aegian inspiration (p. 74). Similar pottery is found also in Phrygia and Mysia (p. 76); and M. Pottier suggests that between early times and the period of the eighth and seventh centuries B.C. Susian influence percolated into Phrygia from the neighbouring lands. The geographical lines of the spread of this culture seem to have been determined mainly by the distribution of copper and gold. Elamite pottery has been found north of the Black Sea in Scythia (Pottier, p. 74).

Without any definite reasons, so far as I understand his report, M. Pottier thinks that, although the designs upon the painted pottery of the Thracio-Phrygian area are similar to those of the Susian ware, the inspiration was independent. However, he thinks that Lydia and Caria, Syria and Palestine were influenced both by Elam and Egypt about the middle of the third millennium. Once one admits the motive and considers the times of the respective diffusions of culture, the process and the lines of spread become clear enough. When gold and copper acquired in Egypt for the first time an arbitrary value they were sought for far and wide, not merely in the Eastern Deserts of Egypt and Nubia, but also in Arabia and Elam, in Asia Minor, in the Caucasus and Turkestan. From Egypt there were two main lines of diffusion of culture—one to Elam and the other to Crete and Asia Minor, from which and from these centres secondary lines of radiation were established.

One of the most striking illustrations of the extent of these secondary radiations is the influence which prompted them, and it is afforded by the remarkable centre of Elamite culture at the little village of Nal (in the Jhalawan district of Kalat state, lat. 27°46', long. 60°14') in Baluchistan (J. H. Marshall, "A New Type of Pottery from Baluchistan," Survey of India, Annual Report, 1904–5, Calcutta, 1908, pp. 105 et seq.; for summaries see Revue archéologique, 1909, p. 156, also Pottier, op. cit., p. 72; Noeting, "Ueber eine prähistorische Niederlassung im oberen Zob-Thal in Baluchistan," Zeitschrift für Ethnologie, 1898, pp. 460–470; also "Ueber prähistorische Niederlassungen in Baluchistan," Td., 1899, pp. 90 et seq.; 1900, pp. 68 et seq.)

The pottery is painted with designs clearly analogous to those found at Susa, of the culture of which it is clearly a contemporary offshoot or a persistent survival. On the evidence supplied by Marshall the latter explanation seemed to be the just one; but Noeting has shown that the Baluchistan pottery occurs in what he calls "Neolithic" sites, and it is quite clear that the Elamite ceramic industry extended as far east possibly in the third millennium. The fact that it was found in association with gold deposits and ancient irrigation works completes the proof of the motives and the identity of the introducers of the ancient civilization. The Baluchistan centre of Susian influence possibly represents a stage in the migration of the knowledge of copper (from Egypt, via Susa and Baluchistan) to India, where an early Copper Age culture
developed on the banks of the Ganges (W. Crooke, *Northern India*, 1907, p. 18: “an age of copper is well marked by finds of implements of remarkable shapes in the Ganges Valley”).

The search for copper or gold attracted these earliest explorers to Elam, to Asia Minor, to Central Asia and Black Sea littoral, and the southern shores of the Caspian and Transcaspia, and to Baluchistan; but it also led them much farther afield. So that, long before the invention of bronze the germs of ancient civilization were planted in Turkestan and along a series of gold-workings from the Oxus to Bukhara, to Issyk-kul and Kulja, to Barnaul, Krasnoyarsk and Minusinsk, which became the centre where for many centuries the civilization of central Siberia flourished in spite of the fact that it was the lure for the greed of a vast continent and the home of strife (W. J. Perry, *War and Civilization,* Bulletin of the John Rylands Library 1318).

But it was not merely the chain of goldien lands along the route from Bukhara to the Yenisei that attracted the miners from the S., but also the gold and jade in the Tarim valley in pursuit of which the prospectors were led on from Kashgar to Kucha past Lop-nor to Suchan, Lintshian and Lashan until eventually they discovered the gold and jade in the mountains S. of Si-nan in Shensi. Setting down to extract this wealth they incidentally planted the germs of the civilization of China. Laufer’s memoir on *The Beginnings of Porcelain in China* (1917) (see also his *Some Fundamental Ideas of Chinese Culture,* *Journal of Race Development* vol. 3, pp. 165-174) affords irresistible corroboration of the fact that “the entire economic foundation of ancient Chinese civilization has a common foundation with that of the West” (p. 175). “It is inconceivable that the (potter’s) wheels of India and China should be independent of those of the West” (p. 175). All the facts brought together by Laufer point clearly to the conclusion that the world at large learnt the use of the potter’s wheel from Egypt (pp. 174-176). Many centuries later “the incentive for the process of glazing pottery was received by the West, originally from those two of the oldest of the four (the Semitic world in comparatively late historical times. The knowledge of glazing rendered the manufacture of porcelain ware possible; yet in this outside influence, but relied on its own powerful resources” (p. 176).

Elamite civilization was diffused to Turkestan long before wheel-made pottery was made, because Pumpey’s excavations revealed the fact that in the first and second of his culture-stages at Anau only hand-made pottery was found.

The routes followed by these early culture-bearers from Persia to central, and to China respectively are now outlined by the remains of ancient irrigation systems. Wherever gold was to be obtained from any of the streams or lakes these wandering prospectors settled to wash the sands for the precious metal: they also irrigated the land in their characteristic way to grow crops to maintain themselves; and they left stone monuments as memorials for their dead. The association of these three classes of evidence, the presence of gold, ancient irrigation and stone monuments, still blazes the paths taken by these ancient prospectors forty or more centuries ago. Detailed statements of the two of these classes of evidence will be found in J. Mouchkeboff’s *Les Richesses Minérales du Turkestan* (Paris, 1878) and H. Moser’s *L’Irrigation au Tibet* (Paris, 1894).

There is evidence of another kind in substantiation of the intimate cultural link between early Egypt, Elam and Sumur, and between them and the Iranian and Turanian domains. The religious ideas and mythology reveal the closeness of the bonds between these ancient centres, and especially the fact that much of so-called early Aryan beliefs and myths are really Egypto-Semitic in origin.

But reference has been made to the intimacy of the early cultural bonds between Mesopotamia and Turkestan because it has a bearing upon one of the most important episodes in the history of civilization—the invention of the alloy bronze and the inauguration of the Bronze Age. We know that before the invention of bronze prospectors for gold and copper exploited the line of deposits of these metals which forms a chain linking the valley of the Oxus to the upper Yenisei. The rich archaeological harvest collected around the sites of these ancient workings establishes this fact. Now if it be true—and the evidence of the most available rocks is probable—the making of bronze was invented with the help of the tin obtained from Meshed. Ancient tin mines were discovered in this region by P. Ogrodnikov (compare Baer, Arch. f. Anthr. [ix., p. 263], quoted by Terrien de Lacouperie, *Western Origin of Chinese Civilization*, p. 322). “Strabo declares that it (tin) was produced in Drangiana, west of the modern Afghanistan, a district partly coinciding with Khurasan, where its presence has been confirmed. It is also found in other parts of Persia, near Astarabad and Tabriz” (C. H. Read, *A Guide to the Antiquities of the Bronze Age*, British Museum, 1904, p. 9). The exact spot where tin has been found at the same period, in the region of the Caspian is indicated by J. de Morgan, *Mission Scientifique au Caucase* (1886).

In her important monograph on *Gournia* Mrs. Harriet Boyd Haves brings forward the following weighty arguments in favour of the invention of bronze in the southern Caspian area. “When the Pumpelly expedition returned from Turkestan in 1904, one of the members brought potsherds indistinguishable at first sight from the brilliantly mottled ware found at Vassiliki (Cretan) during the same season. . . . The strong likeness between the two failes of course was strengthened by intercourse than by accident. Moreover, Dr. Hubert Schmidt . . . reports that a neighbouring tumulus (near the large one in which the pottery was found) gave him a three-sided seal-stone of Middle Minoan type, engraved with Minoan designs—man, lion, steer, and griffin. How shall we explain those evidences of Aegean influence in southern Turkestan? They must be brought in line with other proofs of contact. . . . We see that at c. 2500 B.C. Asia Minor shared with the Aegean the knowledge of bronze . . . we may suggest the probability that, long before tin was discovered in Europe, it was being brought overland through Asia Minor, and also by way of Transcaspia and the Black Sea from distant Khurasan, Strabo’s Drangiana. . . . Excavations at Elizabetpol in Transcaspia have revealed a culture in early contact with the Aegean.”

One of the results of this intercourse between Turkistan and Asia Minor was the introduction into Europe of the appreciation of jade, which no doubt was responsible for stimulating the people of Europe to hunt out and work the supplies of nephrite which occur locally.

Terrien de Lacouperie makes the following statement:—

“Those precious nephrite (polished celts) is found along the route from Transcaspia, its starting point, to the Turkestan, to the Oxus, then S. of the Caspian Sea, in Babylonia and Assyria, along the Northern Asia Minor shores, bordering upon ancient Troy, then passes to the Peloponnesus, where it directs its course to Cretan and not touching Egypt, passes from Greece to Italy, where it is distributed among the Helvetic Lakes, the Megalithic monuments of Armorica, etc.” (Western Origin of Chinese Civilization, p. 34).

Chinese Civilization.—There is no doubt that the cradle of Chinese civilization was in the Shensi province early in the third millennium, and that the inspiration of the early Chinese scholars came from the We, who were exploiting the gold, copper and jade of the mountains S. of Si-nan-fu, and incidentally planting in China the much modified elements of Elamite civilization which had been handed on from one mining camp to another on the long route to China.

The occasional use of jade for seal-cylinders in Babylonia and the value attached to turquoise there suggests that the people who were washing the sands of the Oxus, the Syr Daria, Issyk-kul and the IIi for gold—and the presence of distinctive types of ancient irrigation works on the banks of these waters proves the reality of such exploitation—were also working the Tian Shan range and the neighbourhood of Khotan and Kashgar for jade and turquoise. What strengthens the belief in the reality of this suggestion is the fact that the peculiarly arbitrary and distinctive magical significance which was attached to pearls.
and gold by the early sailors of the Erythraean Sea was acquired also by jade. The only reasonable suggestion that explains the remarkable circumstance is that the materials were acquired by the people of Turkestan from Mesopotamian miners, and that the former came to attach to all the materials for which the immigrants were searching the peculiar attributes which these immigrants themselves assigned only to certain of them. Hence jade came to be regarded, like pearls, as the giver of life and resurrection and as a preventive of putrefaction of the corpse.

The problem that must be solved in the explanation of the symbolism of jade in China is the source of its inspiration. Why should jade be regarded as the giver of life and resurrection, the preserver of the dead and the bringer of good fortune? We know that the pearl was regarded for these same attributes. We know also that the ancient Persian word for a pearl, *margen*, "the giver of life," was adopted in all the Turanian languages; so that the word and the idea underlying it spread E. as far as Kamchatka. The exact identity of the ideas concerning (and the methods of using) jade suggest that they must be derived from the pearl-symbolism, and the tentative explanation suggests itself that the people of Mesopotamia exploited the area in the neighbourhood of the Tian Shan mountains for gold and jade, and so transmitted to the people of Chinese Turkestan ideas of the magical properties of jade which in course of time spread due to the head-waters of the Huang-ho river.

"The mountains south of Si-nan-fu in Shensi Province produced jade, gold, silver, copper and iron in the first century B.C., as expressly stated in the Annals of the Former Han Dynasty . . . the distinguished physician Tao Hung-King (242-336 A.D.), the author of a treatise on *Materia Medica* (*Ming-tu-pih lu*), states that the best jade comes from (Lan-tien): he mentions also the occurrence of jade in Nan-yang, Honan Province, and in the Lu-jung river of Tsinping, also that brought from Khotan and Kaskgar" (Laufer's *Jade*, p. 74).

Laufer denies that jade was imported into China from Turkestan before the commencement of the Christian era; and also to be opposed to the idea that the magical value attached to jade in China was suggested by the West.

While from about the Christian era Turkestan became the chief source for the supply of jade to China, to which Yunnan and Burma were later added, neither Turkestan nor Yunnan came into question in very early times. The jades used in the period of the Chou, and most of those of the Han Dynasty, were quarried on the southern soil of China proper. It was doubtless the Chinese themselves who, being acquainted with jade in their country, probably for millennia, gave impetus and energy to the acquisition and exploitation of jade in the west. Also this case may throw a side-light on the nephrite question of Europe: home-sources do not exclude imports, and scarcity or exhaustion of sources may favor them" (Laufer, *Jade*, pp. 23 and 24).

But Laufer's hypothesis of the origin in China of the special appreciation of jade will not bear examination. The search for gold in Turkestan was certainly begun by people from the South. There can be no doubt that the same people who searched the sands of these rivers of Turkestan for alluvial gold and fresh-water pearls also inaugurated the practice of "fishing for jade.

The proof of this inference is provided by the fact that jade acquired precisely the same reputation and had attributed to it the same remarkable repertory of magical properties as these southern miners associated with pearls and gold.

Dr. Laufer himself puts the matter in its true perspective when he is discussing the problem of European jade (p. 7). His argument is so apt and incisive that it is tempting to use it to demolish his own hypothesis:

"Nothing could induce me to the belief that primitive man of central Europe incidentally and spontaneously embarked on the laborious and arduous undertaking. The motive for this act must be supplied, and it can be deduced only from the source of historical facts. From the standpoint of the general development of culture in the Old World, there is absolutely no vestige of originality in the prehistoric cultures of Europe, which appear as an appendix to Asia. Originality certainly is the rarest thing in this world, and in the history of mankind the original thought is a far rarer occurrence. The problem is in the light of historical facts and experiences, no reason to credit the prehistoric and early historic populations of Europe with any spontaneous ideas relative to jade; they received these, as everything else, from an outside source; they gradually learned to appreciate the value of this tough and compact substance, and then set to hunting for natural supplies."

Substitute "China" for "central Europe" in this admirable statement, and it applies with equal force. For the Chinese had no reasons for attaching a special value to jade until they were inspired to do so by ideas which came to them from elsewhere. Laufer claims that the question can only be settled on the basis of historical fact. His argument also implies that the idea of working jade spread from one centre. In other words, if we accept his teaching, the use of jade in Europe during the early Bronze Age was inspired by events in the Shensi province of China! What historical evidence is there, first, for assigning such a remote date for the exploitation of jade in China, and, secondly, for the transmission of the knowledge of these events from China to Switzerland nearly 4000 years ago?

In Turkestan we find definite reasons for the appreciation of and the commencement of the working of jade. We have also found some evidence to justify the hypothesis that the making of bronze was invented in close proximity to Turkestan. The people who introduced the knowledge of bronze-making into Europe, also introduced the appreciation of jade.

If, however, we accept Laufer's view that Chinese culture inspired the appreciation of jade in central Europe in the second millennium B.C., or even earlier, presumably the channel was via Turkestan. Part of his argument (see above) was based upon the fact that the Chinese jade traffic with Turkestan was unknown before the beginning of the Christian era. But if there was this early intercourse with Turkestan, the fact that the Babylonians or whoever was exploiting the wealth of that country, attached a special value to gold, pearls and jade can hardly be left out of account in considering the origin of Chinese ideas. Is it likely that the exact coincidence between these wholly arbitrary ideas in China and Babylonia respectively were independent of the one on the other? Dr. Laufer himself rightly scouts the idea of such independent development. Hence Chinese ideas concerning jade must have been inspired by the West.

Light is thrown upon these problems by the study of the metal implements found in Siberia and elsewhere. In his admirable *Guide to the Antiquities of the Bronze Age* (British Museum, 1904), Sir Hercules Read summarizes the evidence in an impartial manner:

"At the extremities of the vast area stretching from Lake Balaik to the southern Siberian steppes across the Ural Mountains there are very striking similarities in the bronze artifacts . . . (Don and Dniester, there have been found, generally in tombs, but occasionally on the ground, implements and weapons marked by the same peculiarities of form and by a single type of decoration. These objects bear the closest affinity with those discovered in China; but some of their distinctive features have been traced in the Bronze industry of Hungary and the Caucasus; for example, pierced axes and sickles have been found resembling Turanian and Caucasian forms. The Siberian bronzes have their relationships both in the East and West; but their kinship with Chinese antiquities being the more obvious, it is natural to assume that the entire which they represent is of East Asiatic origin. The presumable antiquity of Chinese civilization (which after all is only a presumption); the continued westward tendency of migration in historical times (which, however, were started by the discoveries in the gold region of the Altai) and therefore tell against Sir Hercules Read's argument); and the fact that the greatest centre of discovery lies far away to the East in the basin of the Yenisei, in the districts of Minusinsk and Krasnoiarsk, are all points which may be urged in support of this view."

To the objections which we have interpolated in this quotation, Sir Hercules Read himself adds others. The Chinese implements are "not of primitive forms":--

Their prototypes are found neither in the Ural-Altai region itself, where some objects may indeed be simpler in design than others but cannot be described as quite primitive; nor as yet within the limits of China itself" (p. 107).
The true solution of the problem will be reached when it is recognized that the basin of the Yenisei and China represent the two termini of a stream of culture which passed N. from the southern end of the Caspian Sea and divided at the Tian Shan range into two branches, one of which passed more immediately to the Yenisei and the other via Khotan and Kashmir ultimately to China. Sir Hercules Read hints at the possibility of this explanation without, however, definitely committing himself to it:

"The similarities existing between the Far Eastern and Hungarian groups will not be fully explained until the Bronze Age of southern Asia as a whole is far better known than it is at present (1904). According to a view which has found some acceptance, the common elements may have been derived from some centre in southern or south-western Asia, from which issued two streams of influence; one passing to the west of the Caucasus, the other to China by a southerly route" (p. 109).

Further, in his account of the Siberian implements, Sir Hercules Read adds:

"The most characteristic ornament represents animals of local species, bears, reindeers, wild goats, etc., the monsters characteristic of the later Iron Age tombs being absent. Sometimes the heads of animals are placed back to back so as to form the guards of daggers, a disposition which has some resemblance to those of daggers represented upon Assyrian monuments" (p. 110).

Correlating all the facts and suggestions brought together by de Morgan, Price, de Morgenstern, Ferghana, and the same authors, we find the general explanation seeming to emerge quite definitely, even if the details still remain to be worked out.

From the third millennium the mines on the S.E. of the Caspian were being exploited and contact was established between Babylonians, Elamites and the population of Turkestan. The northerly extension of Mesopotamian cultural influence established their political power over the Medes and the Persians, and the Assyrians directly and indirectly with the rich metaliferous country stretching along the Caucasus from the eastern coast of the Black Sea to the Caspian. At the same time, from the eastern and south-eastern shores of the Caspian there were drifts of cultural influence to the Aegean and the Black Sea, to Turkestan and China itself.

The invention of the alloy bronze was an event of most moment and it is generally supposed to have been an invention of the Bronze Age. In the history of civilization, the determination of the exact place whence the knowledge of this procedure was diffused to the ends of the earth is therefore a matter of exceptional significance: hence the facts and arguments which point to the neighbourhood of the Caspian early in the third millennium as the place and time of this event have been set forth here in some detail.

Social Organization and Totemism.—One of the most potent factors in shaping the beliefs and customs of the world at large was the result of an ingenious device on the part of the priesthood of Heliopolis to attain their own selfish aims, namely, of increasing their political power over the Nile and also their social status. Until the period of the Fourth Dynasty in Egypt the royal family controlled the whole of the priestly and administrative functions of the State. The king was the high priest and his eldest son the grand vizier. Each of the administrative districts of the State—the nomes—was governed by a member of the royal family. Hence the whole government of the State was concentrated in the hands of one family. But from the earliest times the priesthood of Heliopolis had played an important part in Egypt. They were responsible for the astronomical calculations necessary for the prediction of the annual flood of the Nile, on which the welfare of the whole country depended. At Heliopolis the first kilometre was set up, and in all probability the first solar calendar was devised there. In course of time it became the centre of the solar cult which superseded (or rather adopted and profoundly modified) the Osirian belief in the river as the source of all life. Having built up the solar theology at the end of the Fourth Dynasty the priesthood of Heliopolis made a bold bid for power by putting forward the prophecy that Re, the sun god, would be the father of the first king of the Fifth Dynasty by the wife of the high priest of Heliopolis. Hence arose the custom of regarding the chosen people as "children of the sun" and believing in the virgin birth of kings and gods—arbitrary elements of culture the widespread distribution of which throughout the world is a striking token of Egyptian influence in the upbuilding of civilization. The ingenious device of the Heliopolitan priesthood to seize control of the State was not wholly successful, but resulted in a dual organization of the Government, the Heliopolitan (or priestly) and the Memphite (the old royal) family the civil administration. This splitting of responsibility and control led to a rapid disintegration of the governing power and at the end of the Sixth Dynasty the State was reduced to a condition of anarchy. But the effect of this remarkable experiment in government became widely diffused beyond the boundaries of Egypt; and the dual organization of the community and the use of such phrases as "son of the Sun" were carried far afield, even to Oceania and America. In the whole extent of the regions from Egypt to America we may trace the two well-marked phases of civilization. The earlier represents a form of social organization essentially identical with that of Egypt of the Fifth-Dynasty:—sun-cult; a dual kingship, one ruling family being concerned with secular and another with priestly functions; and a dual division of the State, which even extends to individual villages. It seems probable that the priesthood which originally devised this dual organization realized the danger of the cleavage and the risk of disintegration inherent in it, and introduced the principle of exogamy to maintain the coherence of the community that was split into two conflicting moieties by compelling the members of the divisions to intermarry.

In many places this phase of culture gave place to another derived directly from it by a process of inevitable disintegration following on the splitting off of daughter settlements. In this secondary process the sun-god became known as a war-god: the kingship ceased to be dual, and the dual organization of the State and the village tended to disappear with greater or less rapidity according to local circumstances.

In the early phase of dualism the two rulers were assisted in the administration by a council, the members of which were the representatives of local groups (the Egyptian nomes), usually clans, associated with some animal from which they claimed descent. (The reason for this remarkable belief, known as totemism, is probably to be found in the fact that the earliest Egyptians regarded the milk-giving cow not merely as a foster-mother but as the actual Great Mother of mankind. When the nomes adopted as badges a series of distinctive animals, these maternal functions were attributed to all of them.) Like the kingship this totemic council was also dual, one section being concerned with peace and the other with war. It often happened that the ruling power disappeared and then we find that the people deliberately maintained the council as the proper means of preserving themselves that with which they are familiar. Thus is produced a state of affairs commonly called the dual organization in which the country is divided into two parts with different characteristics. Just as in Egypt one kingdom was known as the white crown and the other as the red, so in many parts of the world one moiety is connected with the colour white (or a light colour) and the other with red (or a dark colour). One is associated with the sky and with peace and is regarded as superior, the other with the earth, the underworld, and war and is regarded as inferior.

A feature of the dual organization is the council of old men—the gerontocracy—which is regarded as of the utmost importance. The various groups of the dual organization in its pure form appear to be what are called totemic clans. The basis of this system is to be found in the doctrine of theogamy, which as we have seen was invented by the priests of Heliopolis to serve their own personal ends.
There was a vast amount of speculation during 1910–20 as to the meaning of totemism, an impartial and full summary of which has recently been published by Dr. Arnold van Gennep (L'Etat Actuel du Probleme Totemique, Paris, 1925). But recent research (and especially the unpublished researches of W. J. Perry, which the present author has been permitted to see and use) makes it abundantly clear that, wherever it is found, totemism has been derived directly or indirectly from the beliefs and practices associated with the ruling classes in Egypt during the Pyramid Age, to which reference has already been made. When one investigates the more primitive forms of totemism and realizes the part played in them by such ideas as matrilineal descent from animals, virgin birth, children of the sun, and the belief in the protective value of animal crests, there can no longer be any doubt as to the derivation of these conceptions from Egypt of the Fifth Dynasty.

In the foregoing account it has been claimed that a very intimate connexion exists between the dual organization and the system of totemic clans. This is not an accidental circumstance, as is often assumed, but is the inevitable result of the conditions under which the dual system arose in Egypt. No doubt this will be regarded as a very heterodox claim; but the facts in proof of it are certain and their meaning quite conclusive. Although the dual organization now survives only in India, Oceania and America, there are marriage customs with a much wider distribution, notably in Africa, which point to the influence of this social system in earlier times. In Australia there are very complex systems of rules to regulate marriage: but in many tribes they afford a very striking demonstration of the original connexion between the dual system and the totemic clans. The dual chieftainship still persists in Polynesia and New Guinea, as it did in Japan until the Shogunate became virtually extinct a few years ago. According to G. F. Röheim (Min, 1915, p. 26) there are very definite traces of the same customs among the Ural-Altaic peoples. He refers especially to the double kingship of the Khazars as being essentially similar to the Mikado-Shogun system of Nippon.

The vast importance of the study of social organization has been emphasized by Dr. W. H. H. Rivers within recent years (Kinship and Social Organisation, London, 1913; History of Melanesian Society, Cambridge, 1914), and in his hands the use of the data relating to marriage regulations and relationship has become a most valuable instrument for investigating the problems of ethnology and the diffusion of culture. (G.E.S.)

**ANTISEPTICS** *(see 2:146).—*During recent years the study of antiseptics has proceeded mainly along two lines—attempts have been made to produce more efficient antiseptics for use in the ordinary way by external application, and chemical substances have been elaborated which when injected into the circulation destroy the microbes with which they are in contact. At the same time many studies have been made on the natural antiseptics by which the body rids itself of infection.

**Antiseptics Naturally Occurring in the Human Body.**—It is well known that we are constantly coming in contact with disease-producing microbes and yet only comparatively rarely does an infection result. It is also well known that an individual who has been living in a secluded spot which was comparatively free from infection, when brought into a city where infection is common, is very much more liable to infection than an individual who had been living in the city. The latter by coming in contact with the microbes has developed a partial immunity to the common infections, so that, while the stranger will rapidly succumb to the infecting microbe, the partially immune person will be able in many cases to resist it. This immunity is due to an increase in the amount of anti-bacterial substances of the body fluids, and to a better organization for the mobilization of the defences of the body towards the point of attack.

In the simplest cases, where microbes are introduced into the body by the instrument which inflicts the wound, there is very quickly produced a dilatation of the surrounding blood-vessels which increases the blood-supply to the infected region. This is followed by an increased transudation of the fluid portion of the blood from the vessels into the infected tissues, and by an emigration from the blood of the white corpuscles or leucocytes, which are amoeboid bodies capable of ingesting the microbes and destroying them.

With some infecting agents such as the typhoid bacillus the fluids of the blood have a great power of killing the microbes, but in most of the commoner infections this power is not so manifest and the leucocytes are the chief agents in their destruction. The quality of the fluids even in these cases is, however, of great importance in preventing the increase of the microbes, and in acting on them so that the leucocytes can readily take them up and complete their destruction. Almroth Wright has shown that in cases of severe infection the power of the blood serum to neutralize tryptic ferment (the antitryptic power) is much increased, and by virtue of this increased antitryptic power the growth of the microbes is greatly hindered in the serum. He has shown also that the alkalinity of the blood is of great importance in retarding the growth of some microbes such as those which cause gas gangrene. He has also shown that the serum will act on the microbes by virtue of its opsonic action so that they can be taken up by the leucocytes and destroyed. These observations on the opsonic power of the serum form the basis for modern vaccine-therapy, which has been of such benefit in combating many infections.

It has been shown that the leucocytes of the blood, and also the leucocytes which exude from the blood into an infected wound and constitute pus, have a very powerful action in destroying the ordinary septic microbes, and that these natural antiseptics have the great advantage over the chemical antiseptics that they act mainly on the microbes which are imbedded in the tissues, and not merely on the microbes on the surface of the wound. In all wounds in which an infection has been established the majority of the microbes are in the tissues well below the surface of the wound, and are quite inaccessible to chemicals applied to the surface.

During recent years research has been directed to the action of chemical antiseptics on the natural defences of the body, and it has been shown that the cells of the body are more susceptible to the microbes of syphilis, and this may be of importance in the future, and more easily administered product of somewhat similar constitution, neo-salvarsan, has revolutionized the treatment of this disease. Following Ehrlich, Morgenroth prepared a chemical substance which had a remarkable affinity for the pneumococcus (the microbe which causes pneumonia), and destroyed it very high dilution, whereas it had little lethal action on other bacteria. It was found that Morgenroth's drug (optochin) lost much of its lethal power on the pneumococcus when injected into the animal body, and also it had certain poisonous effects on the animal tissues, so that in practice it had not been useful. The fact, however, that drugs can be prepared that have a very specific action on one microbe offers some hope that in the future there will be produced chemicals which will be able to destroy the ordinary disease-producing bacteria, without damaging the tissues, and so give us an easy and certain remedy for the common infections.

**Chemical Antiseptics for Application to the Wound.**—Prior to the World War the use of antiseptics in surgery had been largely discarded in favour of "aseptic" methods, in which the aim was to prevent the access of the microbe to the wound. During the war, however, it was found that wounds were infected with septic microbes, and many antiseptic methods...
were employed in the hope of destroying these microbes. At first, antiseptics such as carbolic acid and iodine were used, but they were found to be ineffective in preventing the spread of the infection. Then antiseptics of the chlorine group which were derived from bleaching powder came into vogue, and these were found to be much more useful, although their exact value was obscured by the great advances made in the surgery of the wounds at the same time. These chlorine antiseptics act very quickly on the microbes, but at the same time they are very rapidly destroyed in the wound, so that after about 10 minutes they have lost their antiseptic value. It was the common practice to bathe these wounds with a soapy solution into a septic wound every two hours in the hope of keeping up a constant supply of the antiseptic, but as the active agent is destroyed in about 5 or 10 minutes it follows that for the greater part of the time there was no antiseptic in the wound. Fleming has shown that in all probability the beneficial action of these so-called antiseptics was not in their power of destroying microbes but in their power of aiding the natural antiseptic defences of the body.

In the simplest form these chlorine antiseptics were solutions of hypochlorous acid (ensol) or sodium hypochlorite (Dakin's fluid), but later Dakin introduced complicated organic preparations, such as chloramine T and dichloramine T, which were more stable and contained a greater percentage of the active agent. These later applications have never attained the popularity of the simpler compounds.

Morison introduced into war surgery a procedure in which the wound, after being thoroughly cleansed, was rubbed over with a paste consisting of bismuth, iodiform and paraffin (Bipp). This obtained a considerable popularity, and it was supposed to act by virtue of the iodiform, which is not in itself an antiseptic, being broken down in contact with the blood fluids with the liberation of iodine. Experiments showed, however, that there was not sufficient iodine liberated to act as a lethal agent for bacteria in the body fluids, and it is probable that, like the chlorine antiseptics, this depended largely for its beneficial action on its power of aiding and conserving the natural defences of the body.

The last types of antiseptics to be introduced into war surgery were the aniline dyes. The power of some of these dyes as anti-bacterial substances had been previously investigated. Churchman had shown that gentian violet would kill many varieties of bacteria (those which stain with Gram's method) in a dilution of 1 in 1,000,000, or less, while it had little lethal action on other varieties which did not stain by Gram's method. Another dye, brilliant green, had been used in bacteriological technique for the isolation of typhoid bacilli, owing to its having a less lethal action on these than it had on the other and more common bacteria. Browning introduced into surgical practice another dye of the acidine series, called by him flavine or acriflavine, which had been originally prepared by Benda at Ehrlich's suggestion for the destruction of trypanosomes (the parasites of sleeping-sickness). Flavine differed from all the other antiseptics in that it acted more powerfully in the presence of blood than it did in water. Great hopes were therefore entertained that it would be able to deal effectively with the bacteria in an infected wound. It was found, however, that it was rapidly fixed by the body tissues and by the dressing of the wound, and in practice it was not found to have advantages over the other antiseptics in common use.

Towards the end of the war all the chemical antiseptic solutions fell more or less into disuse and more reliance was placed on efficient surgery and the natural antiseptics of the body. The greatest advance in the treatment of infected wounds was the efficient cleansing of the wound and the removal of all dead tissue, and the immediate closing of the wound so that the natural antiseptic defences could exercise their functions to the greatest advantage. It was found that when physiological salt solution was used the results of this procedure were as good as when chemical antiseptics were employed.

Since the war conditions have been removed antiseptics have largely disappeared from surgical practice, and a return has been made to "aseptic" methods, in which microbes are, as far as possible, excluded from the wound and the natural defences of the body are left to deal with the few microbes which may gain access.

(From 2.148.)

ANTWERP, Belgium (see 2.155).—Pop. (1914) 313,533; but, including Borgerhout (52,126) and Berchem (32,257), total pop. 358,216. The projected grande coupure, or cutting through the neck of the loop in the river Scheldt immediately below Antwerp, was abandoned, and, in place of this scheme, three extensive wet-docks were constructed between 1903-14. In 1913, 7,142 vessels of aggregate tonnage 26,270,000 entered the port as compared with 6,005 of 19,662,000 tons in 1905. The decision, taken in 1895, to change the main entrance to a fortified position by the construction of an outer line of 15 forts and batteries at a distance varying from 6-9 m. from the enceinte was nearly completed at the outbreak of the World War in 1914. A proposal to connect the two banks of the river by a tunnel under the Scheldt was about to be taken in hand in 1912.

On Aug. 17 1914 the Belgian Government left Brussels for Antwerp, and the Belgian army withdrew before the advance of von Beseler's army behind the fortified lines. The bombardment of Antwerp began on Sept. 28 and lasted until Oct. 9, when the city surrendered. Nine-tenths of the population fled, mostly to Holland. Some 300 houses (especially in the Marché-aux-Scelliers, the Avenue d'Amérique and the suburbs near the forts) were destroyed, but the older and more important public buildings (the positions of which were known to the Germans) escaped damage. Under the harsh occupation of the Germans, Antwerp remained practically a dead city. On Nov. 19 1918, the King and Queen of the Belgians entered the city in state and attended a Te Deum in the cathedral. In Aug.-Sept. 1920, the Olympic Games (7th Olympiad) were held in a newly constructed stadium at Beerschot just outside the city.

The Siege of 1914

In the middle of the 19th century, the steady development of the city and its naval installations had made it necessary to enlarge the fortress, and so disquieting were the ambitions of the new French Empire that it was decided to erect a national keep for the defence of Belgium at Antwerp. The new fortress was accordingly built between 1859 and 1870 under the direction and after the plans of the celebrated Belgian engineer, Gen. Brialmont. It comprised: (1) A line of detached forts (forts No. 1 to No. 8 and Fort Merssem on the right bank; Forts Cruyseke, Zwandrocht and Ste. Marie on the left) placed at a distance of about 21 to 3 m. from the agglomeration of buildings, so as to protect these against bombardment. These forts, 2,200 yd. apart, were more complicated in masonry and in earth, were big batteries which embodied the lessons of the siege of Sevastopol. (2) A polygonal enceinte carried round the edge of the city.

With over 1,000 guns the entrenched camp of Antwerp was considered the most powerful fortress in the world. After the lessons of the sieges of 1870-1 and 1877, however, it was considered necessary to extend the fortress's sphere of influence still further, in order to facilitate the operations of the Belgian army when manoeuvring under its protection, and especially to enable it to make sorties in the direction of Brussels or in that of Louvain without being cut off. As the water-line formed by the rivers Nêthe and Rupel considerably impeded such operations between Liére and the Scheldt (that is to say, on that part of the front which was most convenient for them), the forts of

ANTOINE, ANDRÉ—ANTWERP
Waelderhun and Lierre and the Chemin de Fer redhead were constructed S. of the Néthe as a sort of bridgehead. Meanwhile the demands of the port were growing, and the city was becoming cramped within its encinte. It was therefore decided about 1900 to extend the defensive system still further.

The scheme adopted by the legislative chambers in 1906 provided for:

1. The creation of a principal line of defence, composed of detached forts about 5 to 11 m. from the limits of the Antwerp agglomeration, to be constructed by a decision of the town council.

2. The establishment of a line of fortified posts on the right bank of the river, at intervals between the forts.

This line was, on an average, about 2 m. in front of the Rupel-Néthe water-line, thus placing the crossing points of this line out of reach of heavy field artillery. Its total perimeter was 59 m., 46 m. on the right bank and 13 m. on the left, of which 6 m. were protected by inundations.

The forts, 17 in number, were disposed about 3 m. apart, and, in principle, perpendicular to the line of the fortifications. They were armed with one or two cupolas for 15-cm. guns, two cupolas for single 12-cm. howitzers, and four or six cupolas for single 7.5-cm. guns.

The forts and redoubts were constructed entirely of ordinary concrete, with vaults 2-50 metres thick at the crown and surrounded by wet ditches, 33 ft. wide. They all had brick or stone walls, with flanking the intervals with 7.5-cm. Q.F. guns. The garrisons varied from 70 to 200 men.

3. The creation of an entente de siécle on the old fort line, the forts being organized for small weapons. Concrete redoubts were built at intervals of about 200 yd. on the forts, and supporting points of heavy artillery were constructed along the line. The line of defence was to be 20 m. long and 5 to 71 m. removed from the first line of defence.

4. The demolition of the elaborate entente built in 1859 in the immediate vicinity of the town.

The structures and the arming, constructed to resist the 21-
cm. mortars, were not calculated to face 28-cm., still less 30-42-
cm. projectiles.

5. In July 1914 not one of the forts planned in 1906 was finished. Some were still under construction, and these had to be improvised by pouring gravel, iron rods and cement round the cupolas. In some cases cements of cement soaked with water, or even simple sandbags, had to suffice.

The trench system and caissonization of the forts was not established either inside or outside the forts, neither was the machinery in place.

6. For reasons of economy the 15-cm. cupolas had been provided with old guns, formerly on wheeled carriages, which had a range of not more than 8,000 yd., and used black powder. The most recent guns, amongst those of the tradihore batteries, hastily installed, were for the most part without laying instruments. Of the other guns available the most powerful was the 1899 model 15-cm. which had a range of 11,000 yards. Older guns or howitzers, of 12 or 15 cm. were also available, all using black powder. England sent six 4-7 Q.F. guns, mounted on armoured railway trucks, and, in the last days of August, 40 Q.F. guns. No provision for laying instruments or fire and no observation posts existed, and the necessary survey work for firing by the map was incomplete. There were ten aeroplanes engaged for the observation and the field army together.

The supply of ammunition was extremely modest, the 15-cm. guns being provided with 800 rounds, the others with only 125. Some French ammunition was hurriedly obtained, but, not being designed for the guns, it was simply dumped in the forecourt of the forts. The garrisons were chiefly of the oldest classes. The Lebel rifle with which they were armed was strange to them and they were entirely ignorant of the machine-gun. The men of the fortress battalions which garrisoned the intervals had had no military service for 10 years or more and their fighting value was very low. The cadres were entirely inadequate.

Unfinished works, concave and concentrated, proof only against projectiles of 51 cm.; obsolete artillery, lacking in observation-posts and in munitions; a garrison full of goodwill but with inadequate cadres and untrained in the handling of modern weapons—such were the real means of defence of the legendary fortress of Antwerp in 1914.

None the less the Belgians displayed, from the moment their territory was invaded, the utmost activity in preparing it. The unfinished forts were put in a state of defence by any means that came to hand. The aprons for the cupolas were banked up as best they could. Distribution systems were created for motive power, lighting and telephones. The immediate protection of the forts was therefore made so good, as it made the works very visible. The inundations were prepared. Forts and redoubts were united by continuous wire. In the rear infantry trenches were constructed, but these inevitably showed well above ground on account of the water-level in the soil, and the shelters, which were none too numerous, were made merely with logs. The reserve artillery of the fortress was established in battery positions, which gave an average of five old-pattern guns, firing black powder, per km. of front.1 A supporting position along the whole length of the Néthe was put in hand. The old fort line, and even the enceinte (which had been partly demolished), were also organized as far as possible.

The unfinished state of the fortress and the mediocrity of its armament formed a serious handicap to the important part which Antwerp was destined to take in the operations.

1. As a great commercial metropolis, always abundantly supplied with products of all kinds, Antwerp was an obvious centre for military depots and stores. Containing all the army's arsenals and supply magazines, it was a base of operations from which the army could under all circumstances allow itself to be cut off.

2. By reason of its situation Antwerp offered to the Belgian field army a stronghold from which it could safely fall at any time it chose, to threaten the lines of communication of the German advancing army in the north of France.

3. Through Ostend and Zeebrugge Antwerp had easy means of communication with England. Under the shelter of the fortress and the Scheldt English troops could safely land in Flanders, act in liaison with the Belgian army, operate against the German lines of communication, protect the Pas de Calais coast with its sea traffic, vital to England, and prevent the Allied left wing from being turned and enveloped.

To fulfill these important missions the fortress should have been complete and well manned. Failing these conditions, it was of no importance save for the presence of the Belgian field army within its walls.

The Belgian army had fallen back in the direction of Antwerp when, to avoid envelopment by the German I. and II. Armies, the Néthe position had to be evacuated (Aug. 18–20). Hence, too, after the sortie battles of Aug. 25 (Eppelgem, Hofstade, Werchter) and Sept. 9–12 (Aerschot, Haecht, Louvain) undertaken for the purpose of co-operating in the battle of the Frontiers and that of the Marne, the army returned in each case to the fortress, resolved to stay there as long as its communications with the sea were not in danger.

When the German I. Army took Brussels through and past Brussels on its way to France, it dropped the III. Res. Corps (v. Beseler) to face northward as a flank-guard against the Belgian field army at Antwerp. With some additions and changes, Beseler's force2 remained on the defensive, fulfilling this duty on the line Grimbergen-Over de Vaert-Aerschot.

On Aug. 25 and again on Sept. 9 it had to meet serious sorties of the field army in Antwerp, and on the second of these occasions its situation was at one time critical. After this, for a few days, the front was quiet. But towards Sept. 20 reports began to come in of important German transport moves and of a quantity of very heavy artillery moving on the roads leading

1. The artillery of the field army of course excluded.

2. Till Sept. 8 Beseler remained under command of I. Army. From Sept. 8 to Sept. 10 his force was under the VII. Army headquarters. Finally on Sept. 17 the force was designated "Armeegruppe Beseler".

(C. F. A.)
from Maubeuge to the region N. of Brussels. The powerful materiel which had laid in ruins the forts of Liège, Namur and Maubeuge in succession was in fact now on its way to Antwerp. Soon it was established in position in all the region between the Dyle and the Grande Nèthe, from Boortmeerbeek to Heyst-op-den-Berg. The heaviest ordnance, 30-5-cm. and 42-cm. howitzers, had not only demolishing but also ranging power. They could install themselves in perfect safety beyond the extreme range of the Belgian guns, and regulate their fire as if on the experimental range.

The total artillery strength of the Germans before Antwerp was:

**Field Artillery**
- F. Gun 25 batteries: 150 pieces
- F. How. 6 ": 36 "
- Total: 186 pieces

**Heavy Field and Siege Artillery**
- Guns 10 cm. 6 batteries: 24 pieces
- 13 cm. 4 ": 16 "
- 15 cm. 2 ": 8 "
- Long guns: 48 pieces

**Howitzers**
- 15 cm. 18 batteries: 72 pieces
- 21 cm. 12 ": 48 "

**Super-heavy Howitzers**
- German and Austrian 30-5 cm. 4 batteries: 9 pieces
- German 42 cm. 2 ": 4 "
- 13 pieces (C. F. A.)
On Sept. 27 the German operations assumed the character of the beginning of a siege. The town of Malines received a violent bombardment and was evacuated. The artillery deployment of the attack was completed, and fire opened on the 28th.

The Army Group Beseler comprised at that time the 37th Landwehr Bde. between Alost and Termonde, where it had served in flank guard since Sept. 14; the 4th Ersatz Div. (arrived from Lorraine on the 26-27) between Termonde and the Willebroek canal; the Marine Div. between this canal and the Dyle about Malines; the III. Res. Corps from the Dyle to the Antwerp-Aerschot railway (35th R. Div. on left, 6th R. Div. on right), and the 26th Landwehr Bde. N. of Aerschot, with a group furnished by the III. Res. C. further to the right front at Westerlo.

The specialist troops, besides the medium and heavy artillery already alluded to, were two regiments and some additional units of pioneers, four railway companies, three kite balloons and a flight of aeroplanes and an aircraft, a survey section and two searchlight sections. General von Beseler himself was an engineer general and had been inspector-general of pioneers.

Field-Marshul von der Goltz, Governor-General of Occupied Belgium, had at his disposal some brigades, of which the 1st Reserve Ersatz Bde. and the 1st Bavarian Landwehr Bde. joined the Beseler Group directly, while the 31st Landwehr Bde. watched the left rear between Alost and Ninove, and the 35th Landwehr Bde. the right front near Beverlooc Camp.

Siege Operations. It at once became clear that the attack was being concentrated on the south front of the fortress. The attack project elaborated by the Germans in peace-time had made the east front the objective. On the other hand, an attack against the west front would have had the advantage of isolating the Belgians from Allied support. But von Beseler had not the necessary forces to prosecute a siege on this side while still covering the communications through Brussels against a sortie. In spite, therefore, of the fact that the Neth and its inundations lay behind the fort line, he had decided to attack the south front.1 Trusting in the three-proved powers of his weapons of attack, he set out to spare his infantry, to crush and throw into confusion the lines of defence by gunfire, ruin the mechanism of the organs of defence in the forts by methodic hammering, controlled by aircraft, destroy the guns in their cupolas and the garrison in their shelters—more certainly than would have been possible if they had been dispersed—before giving them a chance of fighting. These results attained, he would then cautiously advance his infantry and gain a footing in the shattered forts and pulverized lines of defence.

The Belgian troops were thus faced with the prospect of waiting stoically and in obscurity, without hope of repose, under the fires of a cyclopean bombardment, till the moment when they should be blown up or crushed at their posts.

Under such conditions they could not hold out very long. It was essentially a question of the number of mortars and the quantity of munitions possessed by the assailant and of the destructive power of each separate projectile. Actually this unequal struggle lasted 10 days and nights without truce, and this time was infinitely precious in retarding the moment when the Germans—rid at last of the menace of the Belgian army on their right rear—could freely and with better chances renew their great effort to reach and envelop the left flank of the Franco-British armies.

On Sept. 27 the Belgian field army was distributed on the most dangerous sectors as follows: The 1st and 2nd Divs. between the Senne and the Nethé from Willebroek to Lierre with the 5th Div. in reserve N. of the Nethé; the 6th and 3rd Divs. between the Senne and the Scheldt; the 4th Div. at Termonde and the cavalry division about Alost-Witteren to cover the communication between Antwerp and the sea.

On the morning of the 28th the German cannonade was let loose along the whole front between Termonde and Lierre. Under cover of this the infantry got into contact with the outposts of the fortress. The Belgian guns replied with vigour.

Between the Scheldt and the Senne Belgian detachments energetically repulsed their assailants (4th Ers. Div. and Mar. Div.), notably on the outskirts of Blaesveldt (S.E. of Fort Breendonck). But E. of the Senne towards noon, the super-heavy artillery came into action and began by engaging Forts Waelhem and Wavre Ste. Catherine.2 At Fort Wavre Ste. Catherine the first 42-cm. shell pierced a concrete vault 24 metres thick. At 7 P.M. the gallery of the gorge front was demolished. Other vaults, including those of the fire-control room, suffered the same fate; a cupola was jammed, and the left traditore battery crumbled into the ditch. The other forts suffered less. The firing, after a pause in the evening, continued with intensity all through the night on most of the forts. On the 29th, W. of the Senne renewed attacks, especially heavy about Blaesfeldt, were repulsed. Between the Senne and the Nethé the cannonade was even more violent than on the previous day, both the trenches in the intervals and the permanent works being engaged. From 5 A.M. Fort Wavre Ste. Catherine (which in fact was the point selected by von Beseler for the break-through) received 42-cm. projectiles at regular intervals of seven minutes, not counting those of 21 and 30-5 cm.

It is difficult to imagine the terrible situation of a garrison subjected to such a bombardment. The arrival of a 42-cm. projectile is announced by a deafening roar. When it bursts in the masonry the whole mass of the fort shakes violently and seems to sink in the earth and to oscillate back to its original level. The blast throws men against the walls. Palls of fire and clouds of dust cause violent sickness and sometimes suffocation. Under such conditions, and in close confinement, it is easy to see why the men lost not only their powers of action but even, it seemed, their reason.

The men’s quarters were destroyed, fires broke out, the air became unbreathable and the greater part of the garrison took refuge on the berm of the ditch. A 42-cm. projectile went through the dome of one 15-cm. cupola, exploded, and tossed the vauvours to a distance of about 30 feet. The second 15-cm. cupola was put out of action by a 30-5. The other cupolas were either destroyed by being laid bare or made inaccessible by the obstruction of their galleries. The magazine was hit by a shell and blew up. The double casemate of the capital was completely ruined.

By 11 A.M. the fort had all its guns out of action and all means of defence destroyed. The survivors of the garrison were authorized to evacuate it as fire rendered it untenable. Forts

1 His request for additional forces wherewith simultaneously to operate west of the Scheldt was refused by headquarters.

2 The artillery of medium and heavy calibre was deployed mostly along the Malines–Heyst-op-den-Berg road, the rest behind Malines, at ranges of 3,500 to 7,000 yards from the two first and 5,000 to 9,000 from the two last-named forts. Of the super-heavy artillery two 30-5-cm. batteries (range 9,500 and 10,500 yards) engaged Fort Waelhem and Chemin de Fer ou Duffel redoubt; a 30-5 battery (8,500 yards) and a 42-cm. battery (11,500 yards) attacked Fort Wavre Ste. Catherine; an Austrian 37-5-lb. battery (range 8,800 yards) Fort Roningenbroyck, and a 42-cm. battery (range 9,000 yards) Fort–Lierre. All these were two-gun batteries except the Austrian, which had four.

The ranges here given are approximate. For positions see map.

(C. F. 21.)
part in the evening in repulsing the attack on the intervals. 8
Fort Lierre, after six hours' uninterrupted bombardment from the 42's, repulsed an attempted assault early in the evening. The same night (1st-2nd) the Germans tried in vain to pierce the interval between Fort Lierre and the Tallaert redoubt. 4

Between the Scheldt and the Senne the German infantry made no move on this day. The artillery, however, kept up a continuous hammering on the front of the Belgian 3rd and 5th Divs., and especially on Fort Breendonck.

On Oct. 2 the Belgian 1st and 2nd Divs. crossed the Nèthe and pushed forward to regain the intervals lost during the night, but were checked by violent artillery fire, and King Albert thereupon ordered the German forces to continue to force the way to the north of the Nèthe, and had all crossings destroyed.

The evening was marked by the death-struggle of Fort Waelhem. Here the recent strengthening of the structure had consisted chiefly in overlying one metre of concrete on the old brickwork of 1881, and, according to the Germans, the 21-cm. shell falling in large numbers on the fort contributed as much to its ruin as the 30-5's of which calibre the fort received 30 effective hits out of 550 fired. The Tallaert redoubt and Fort Koningshoyckt were evacuated, being in ruins, the first-named owing to the explosion of a magazine, the second owing to the havoc of the shells. On the fall of Fort Waelsem, Catherine, the 42-cm. battery hiterto engaged against that fort was turned on to Fort Koningshoyckt, superposing its effect on that of four Austrian 30-5's. At Fort Lierre, after the fruitless attack of the previous day, the German artillery opened fire at 7:30 A.M. and battered successively all the organs of the fort. Several aeroplanes aided in directing the fire, and here the single 42-cm. battery engaged obtained a higher percentage of hits than elsewhere (32 out of 175 rounds). All the cupolas which put out of action, and all the chambers had to be evacuated in turn. By 7:15 P.M. the fort was practically destroyed and shortly after 8:30 it was evacuated. The Germans did not occupy it till next day.

On the 3rd the small Dufif (Chemin de Fer) fort, armed with six 57-cm. cupolas, on which the German artillerymen no doubt disdained to waste a 42, 8 held the enemy engaged the whole day until its munitions were exhausted. The commandant then blew up his defences and brought back his guns and his wounded to the N. bank of the Nèthe. The German infantry of the Marine Div., which advanced during the day and the night, occupied the ruined redoubt early on Oct. 4. The Belgian troops now began to be seriously disheartened. The forts, in which their confidence—though misplaced—had been supreme, had in a few days been shattered under their eyes by the blows of a monstrous artillery, and they knew that their field artillery had nothing 4 but its own brave audacity with which to carry on the struggle. All its efforts were concentrated on thwarting the enemy's active preparations for crossing the Nèthe, where the infantry hastily erected new lines of defence.

The events of these days had left no illusions as to the fate in store for Antwerp's fortified positions. It had been proved that the 42-cm. or even the 30-5-cm. shell would pierce a non-reinforced concrete vault of 25 meters or the 21-cm. (93 in.) chrome-nickel-steel domes of the cupolas. Once fire had been opened on a fort it was a question not of days but of hours to put it completely out of action. This being so, the idea that the entrenched camp of Antwerp could constitute a definite place of refuge for the army and the Government had to be abandoned once and for all, on pain of involving the army in the surrender of the fortress. But another and a far more serious

1 According to the German account, the defenders were even able to counter-attack on this part of the line.

2 Tschischwitz says that the existence of the Tallaert redoubt came as a surprise to the Germans.

3 According to the German account, the light flanking guns were still in action when the fort was stormed. Authority had however been given to the commandant (see above) to evacuate it. The fort received 34 hits (out of 500 rounds fired) from super-heavy calibres. Observation difficulties, due to the country, seem to have made control of fire unsatisfactory.

4 Ammunition supply had become a matter of anxiety by the evening of Oct. 3.
menace threatened the army more and more as the days went on. For a fortnight past the "Race to the Sea" had been in progress in France. Each side, hoping to envelop the outer flank of the other or seeking to protect its own flank from the same fate, was being led by a series of parallel and practically synchronous efforts to displace the centre of gravity and the decisive point of the campaign towards the sea. Thus by the end of Sept. the battle-front had been extended from the Oise to Arras and Béthune, and fresh German masses were traversing Belgium in a westerly direction.

The real peril to which the Belgian army was exposed lay in the possible failure of the Allied left to gain on the enemy's right and join up with the Belgians on the Scheldt. Yet this junction must be effected at all costs, even if the fortress had to be abandoned in order to get into contact with the Allies.

The King was strongly in favour, however, of holding the fortress until the last extremity, in order to bind the troops and material now concentrated before it, and also to gain the maximum of time for the formation of a Franco-British-Belgian front on the Scheldt and the Dender—the natural rampart of the coast, the Straits and England. To prevent the Germans from reaching the coast would be an inestimable service rendered to the Allies, and the King was determined not to relinquish the idea save in the last resort. Every day gained at Antwerp meant a French port saved—to-day Boulogne, the next day Calais, the next Dunkirk—and the withholding from the Germans of the Straits of Dover, the most important maritime artery in the world.

Mr. Winston Churchill, then First Lord of the Admiralty, fully realized the capital rôle which the fortress might play in the war. With great foresight and initiative he had drawn the attention of the British War Office to the strategic importance of Antwerp in the beginning of September. In the first days of Oct. he came in person to the besieged fortress to take stock of the situation. The Belgian Command gave him a frank statement of its intentions, and King Albert informed him personally of the rôle he proposed for the Belgian army on the extreme left wing of the Allied front. Henceforward, in agreement with Mr. Churchill returned in all haste to London to push forward the immediate dispatch of all the troops the French and English Governments could spare to Antwerp and Ghent. It was urgently necessary (1) to guarantee the effective union of the Belgian army with the general Allied front and (2) to bring about this union on a level with Antwerp, or, failing this, on a line as far east as possible with its left resting on the Dutch frontier or the coast, so that the enemy could in no case seize and envelop the Allies' extreme left wing.

Given the double aim which the King had in view, that of holding Antwerp as long as possible and not allowing himself under any circumstances to be cut off from the Allies, there was no time to be lost in transferring the main base of supplies from Antwerp to Ostend, whence the army could carry out its subsequent operations in concert with the Allies. The transport of materials and supplies and the evacuation of the manufacture and storage establishments, of the wounded, the prisoners and the recruits therefore commenced on Oct. 1. Although the only through railway connexion between the E. and W. banks of the Scheldt was that by way of Willebroeck, Puers and Tamise, ranging the Allied front, both the Belgian and the French armies were directed to follow one another night after night, with all lights out, until Oct. 7 without attracting attention. West of the Scheldt the evacuation transports and convoys were protected by the 4th Div. round Termonde, and the Cavalry Div. round Wetteren.

A first attempt on Termonde had been made on Sept. 26 by the 37th Bde. advancing from Alost down the left bank of the Dender. Not only had this been hung up at Gyseghem, half-way, but Alost itself in its absence had fallen to an attack by Belgian forces from Wetteren. The 27th and 28th were taken up in recapturing Alost, which was then effectively held, though the garrison was "constantly and severely worried by cavalry, cyclists, armoured cars and armoured trains" in the words of the German account. A detachment of the brigade was sent up to watch the S. side of Termonde, and one from the 4th Eng. Div. was similarly posted (not British Assistance.—The immediate result of Mr. Churchill's personal intervention was the arrival at Antwerp, on the evening of Oct. 3, of a brigade of 2,000 men of the British Royal Naval Division. The appearance, at dawn on the 4th, of these the first Allies the Belgian soldiers had set eyes on during the two months of the yawned a wholesome enthusiasm aiding the dispirited defence troops. Unhappily, this assistance could be no more than a moral stimulus for a fresh burst of energy.

Meanwhile, the German infantry E. of the Sèna advanced steadily as near to the Nèthe line as the Belgian fire permitted, while the medium and heavy artillery moved up to new positions, and the super-heavy batteries, freed by the fall of all works between Waalhem and Fort Lierre inclusive, got into place to attack Fort Breendonck on the left flank and Fort Kessel on the right. Three German 30-5 batteries W. of Hornbeek engaging the former, and the Austrian 30-5's of Heykant and of 42 cm. battery 1 of the right of the latter. On the other hand, the six pieces concentrated upon Fort Kessel at ranges of 9,000-9,300 yd. quickly finished their work, the place being ruined and evacuated just before midday. It was not until the 6th, however, that fire was seriously directed upon Fort Breendonck.

Gen. von Beseler's original scheme was that each unit on the III. Res. Corps front should strive on its own account and at its own time to obtain a foothold beyond the Nèthe, while the Marine Div. remained echeloned back on the left, and the 26th Landwehr Bde. advanced on the right as close to Fort Kessel as possible. The fire directed upon the half-exposed left of the 5th Res. Div. should have been so directed that the right of the Marine Div. should also attempt to advance. In this it was unsuccessful, and during the 4th the whole of the 5th Res. Div. and part of the 6th could do no more than approach the water-line.

On the right of the 6th Res. Div., on the contrary, a bold advance carried the Germans into Lierre, and there began in that town a prolonged and fierce struggle, the British Marine Bde. deployed along the little Nèthe and the 5th Belgian Div. on the Nèthe between Lierre (excl.) and Hht Ven (excl.) commanded the enemy's guns of the 4th Res. Div. and the German divisions of the 3rd Landwehr Bde. which, on the fall of Fort Kessel, had pushed up to Klosterehyde.

On the evening of Oct. 5 the German force in Lierre was still pinned down by the fire of the Marine Bde. Further south, under cover of a very heavy bombardment, they had succeeded in crossing the river, but were held a short distance beyond it, along the road from Hht Ven to Lierre, with only precarious communications behind them.

On Oct. 6 at dawn the 5th Div. tried, by a general counterattack, to throw the enemy back to the S. of the Nèthe. But with the mass of their forces now in the Nèthe valley, the counter-attack was doomed. The German guns vigorously supported it, and a determined attack near Ringenhof was for a moment successful and produced a crisis in the German line. But no more could be done. The assistance of Fort Brochom was at an end, since on this day it was taken under fire by the 42-cms. and the Austro-30-5's, which had ruined Fort Kessel and then advanced to their third positions at Vytohok and Königshoek respectively. More and more German infantry was, by one means or another, got across the Nèthe, holding up both the right of the 5th Div. and the 6th Div. and the English Marine Bde. fell back little by little in the afternoon without fighting) at Buesnode. The whole force on the left was placed under the 4th Eng. Div.'s staff, but until the arrival of further troops from the governor-general's forces (1st Res. Engs. Bde. nothing could be done. On Oct. 4 the arrivals of these troops, behind which the 1st Bn. Lw. Bde. was also coming up, released the 37th Lw. Bde. from Alost, and an advance was made by this brigade to Schoonarde on the Scheldt, with a view to forcing the passage there and reaching Termonde from the rear. On the 4th, 5th and 6th, the Bde. attempted to do so, but were repulsed by the defenders, and throughout the critical days the Germans were unable to interfere with movements in the Lokeren region.

(C. F. A.)
to the line Contich-Bouchout, where civilian labourers and recruits had dug some rough trenches. Meanwhile, along the Scheldt, the enemy's attitude was becoming more and more aggressive in the efforts to gain the crossings at Baesrode, Termonde, and Schoonaerde. The situation of the Belgian 4th Div., on a front of 138 m., began to be serious. There lay the gravest danger which threatened the Belgian army—that of being invested in the fortress. The 6th Div., which with the 3rd Div. still held the fort line between the Wilhelroec canal and the Scheldt, now received orders to cross the Scheldt at Tamise to reinforce the 4th Div. and safeguard the army's communication with the west.

Withdrawal of the Belgian Field Army. The defence troops were becoming extremely fatigued, the bravest among them being daunted by the uninterrupted bombardment and the persistent feeling of helplessness in the face of the weapons which had pulverized forts and lines of defence in succession. Soon the enemy would be bringing up his batteries to bombard the city itself. If it had taken only a week to reduce the principal line of resistance constituted by the modern forts on the S. of the Néthe, still less would suffice to break up the old forts of the inner line. The fortress could now offer no prolonged resistance. Moreover, all hope of linking the Antwerp front with that of the Franco-British armies had to be abandoned. Two new English naval brigades, recently formed, had arrived in the fortress on the 5th, bringing the effective of the Royal Naval Div. up to 10,000 men; a French naval brigade had been moved from Dunkirk to Ghent and the British 7th Div. and 3rd Cavalry Div. under Gen. Rawlinson had landed at Zeebrugge and Ostend. Had these troops arrived a few days earlier a combined operation against the left wing of the besieging force 'might have changed the face of the war. But it was too late,' as Mr. Churchill said: "A week earlier, the result would have been a certainty ... a little later 200,000 men could not have carried the operation through."

On the one hand, the Germans were threatening the line of retreat through Termonde. On the other, liaison with the Allies was compromised, for the German right wing in France was now hardly more than 30 m. from the sea, whereas the distance from the Néthe to Nieupot was 85 miles. This being so, one consideration now dominated all others—the Belgian army must avoid being surrounded. On the evening of Oct. 6 the King decided to separate the lot of the main body of the army from that of the fortress, and gave orders to cross to the left bank of the Scheldt during the night of the 6th-7th. The troops were then to continue their march westward. It was high time, for, on the 7th, the Scheldt was forced at Schoonaerde, the Germans making every effort to throw back the 4th Div. on Lokeren.

The fortress was still to be defended to the utmost by Lt.-Gen. Deguise, the governor. The garrison proper (personnel of the forts and fortress troops) with the 2nd Div. and the British Naval Div. some 50,000 men, were more than enough to do what could be done with the remains of the fortress.

The Final Resistance. On the 6th Fort Broechem, battered all day by four 30.5's and two 42-cms., had been put out of action and dismantled. The improvised line Aertselaer-Contich-Bouchout was merely a row of light shelter-trenches, lacking in depth and with both flanks in the air. General Deguise considered it too risky to commit his forces, very inferior as they were, to a determined defence of this exposed position. He therefore placed the 2nd Belgian Div. and the English Div. on the line of forts No. 1 to No. 8. These two divisions stoically endured there the usual bombardment throughout the days of the 7th and 8th. Meanwhile the main body of the Belgian army

1 The German official account criticizes the inactivity of Gen. Paris in not seizing the opportunity offered by the success at Ringen. Whether this criticism be well founded or not it shows that the position at that moment was regarded by the German command as critical.

2 On the night of the 6th the German line ran from a point S. of Fort Broechem, along the Little Néthe and in advance of the Néthe, to a point about 1 m. W. of Duffel Station. The Marine Div. was still short of the general alignment, not having crossed the river. On its left, the 4th Ersatz Div. faced the line of the south-western forts, while Fort Breendonck was beginning to be subjected to bombardment. The left of the 4th Ersatz Div. was at St. Amand and Baesrode on the Scheldt, in touch with the forces operating at and above Termonde. On the extreme right, detachments were advancing in the direction of Maasenhoven redoubt and Sanktoven.

(C. F. A.)
was moving between the Scheldt and the Dutch frontier, seeking contact with Rawlinson's force and the French Naval Bde. which were collecting towards Ghent.

In the afternoon of the 7th, under instructions from O.H.L., Gen. von Beseler informed the governor of his decision to bombard the city of Antwerp, commencing at midnight, in default of previous capitulation. This attempt at intimidation had not the smallest effect upon either Gen. Deguise or on the Communal Council which, convoked by the governor, declared itself to be "willing to accept the consequences of prolonging the defence to its extreme limits," and assured him, moreover, that it never would try to influence the decision of the military authorities responsible for such defence.

The bombardment began at midnight. It was directed especially on the gates of the enceinte. Certain quarters of the town were attacked by long-range guns. On the same night (7th-8th) part of the III. Res. Corps pushed its patrols up to the fort line of defence.

On the 8th, Gen. Paris, the English general, and Lt.-Gen. Dassin, commanding the Belgian 2nd Div., came to the conclusion that resistance to a determined attack on the following day would be hopeless. On hearing this and also that Gen. Paris, after telephonic communication with the British Admiralty, had received orders to bring away the Naval Div., Gen. Deguise at 5.30 p.m. gave up the idea of holding the fort line of defence any longer, and decided to take advantage of the night to withdraw all the troops occupying it to the left bank of the Scheldt.

The orders were:

(1) The British Naval Div. to cross in the night and entrain at St. Gilles Waes for Ostend.

(2) The 2nd Belgian Div. to accompany the British Div., covering its entrainment at St. Gilles Waes against the German troops reported near Lokeren (see below), then to march westward and try to rejoin the rest of the Belgian army.

(3) The forts still intact to defend themselves individually to the utmost.

(4) The enceinte to be handed over to the Germans when they appeared before it, in order to save the city from unnecessary damage.

A force of some 20,000 men of the garrison troops, under Gen. Deguise himself, to hold out as long as possible in the entrenched camp formed by the Scheldt and the forts of the left bank.

These movements took place in the night of the 8th–9th without being disturbed by the Germans (who had no suspicion of them), but not without a good deal of confusion. Meanwhile the bombardment of the city continued.

On the 9th the Germans had succeeded in forcing the passage of the Scheldt at Lierre and Melle. The advance was pushed to within 2 m. of Lokeren, where sharp resistance was again met. The Belgian army was in fact streaming past the front of this small force in several columns; neither side, however, was in a position to take advantage of the disarray. The Germans, owing to the tactical, the Belgians owing to the strategical risks that this action would have involved.

Next day the Belgian divisions, though the enemy did not know it, were past the reach of attack and in touch with the French and British forces at and north of Ghent, leaving no baggage or stragglers to be picked up, since all impediments had been removed in the transfer of base to Ostend several days earlier.

On the 9th, therefore, the three German brigades, now followed by the rest of the 4th Ers Div., struck a blow in the air, while the 1st Res. Ers. Bde. from Alost advanced on Ghent, and at Melle became involved in a very heavy fight with the French Naval Bde. and some Belgian batteries (Oct. 9 and 10). On the 10th, wheeling inwards to invest the fortress, and thus turning their backs to the Belgian field army, the five German brigades N. of the Scheldt pushed on to the line St. Gilles Waes-St. Nicolas, Ketternum. But instead of the expected main body of the Belgians they only encountered the 2nd Belgian Div., which passed under fire of their guns at Moerbeke westward and the two last battalions of the British Naval Div., which were caught at St. Gilles Waes and forced over the Dutch frontier.

Thus did the greater part of the prey which the Germans counted on capturing at Antwerp escape them.

Meanwhile Gen. Deguise was preparing to defend the entrenched camp on the left bank of the Scheldt. But his remaining troops were of mediocre quality. The men of the fortress battalions were old, their officers few—hardly one per company—and nearly all either reserve officers or newly commissioned. The N.C.O.s were scarce and did not know their men. In fact, Gen. Deguise had 20,000 men in uniform rather than 20,000 combatants. On troops such as these the fury of the bombardment naturally had produced a great effect, and the departure of all field troops, and that of the English whom they had welcomed so hopefully, led them to look upon themselves as so many units written off. During the whole of the 9th and 10th their lines were crossed by crowds of civilians, who, carrying their families and their furniture and driving their live stock in front of them, filled all the roads and routes leading westward, repeating as they went the stories, a hundred times magnified, of Visé and Louvain, of Dinant and Aerschot.

The spectacle of this deplorable exodus completed the depression of the soldiers. It was no longer possible to expect this almost shepherds flock of men at bay to defend themselves in open trenches when they had seen armour and concrete ruined in a few hours.

On the evening of the 9th Gen. Deguise, knowing that the Germans were near Lokeren and believing, through an erroneous report, that they had also encamped the night at Antwerp itself, became convinced that no further organized resistance was possible. Officers and units were allowed to leave the fortress at will and were to attempt to rejoin the field army. Many acted upon this and some succeeded, the rest taking refuge in Holland. On the 10th the general sent a flag of truce to Gen. von Beseler to enquire the conditions of surrender. But meantime the civil authorities, seeing the city to be empty of troops, had acted on their own account. The situation was grave. At about twenty points fires had been started by the bombardment. The waterworks at Waehem on the Kupel having been in German hands for a week, the firemen could not undertake to master the flames in the fire areas. With a sudden violent wind the whole city might be set ablaze.

To save the city from a disaster, which could be of no advantage from a military point of view, the leading townsman had sent a deputation to Gen. von Beseler to obtain a cessation of the bombardment, and on the afternoon of the 9th an agreement was signed suspending the bombardment on condition of the surrender of all the works of the fortress the following day at noon. Gen. Deguise had no choice but to ratify this agreement. Although the city was immediately in ruins, and the fall of Antwerp, the material strategic gain to the Germans was far less than had been anticipated. Although in military stores and economic resources their booty was considerable, not only had the whole of the Belgian field army made good its escape, but even the fortress troops were left to adorn the German triumph. As to the works which had not been attacked, they were empty and in most cases rendered useless by their commanders.

Antwerp—Port Arthur—Verdun.—The rapid fall of Antwerp in 1914 may seem astonishing when compared with the resistance of Port Arthur in 1904 and that of Verdun in 1916. It is necessary, however, both in appreciating the resistance of the Belgian fortress and in deducing technical lessons from the siege, to compare the conditions of the three cases in some detail.

Although Port Arthur possessed no cupolas and several of its forts were unfinished, yet the Russians had six months' leisure to prepare, not a line, but a zone of defence 3 m. deep, in which forts, trenches and redoubts formed a tangled system, cleverly applied to very difficult ground. Dug out of hard rock, these entrenchments offered an exceptionally good resistance to the engines of destruction. The artillery of the defence was ample and well distributed in the intervals. Finally, the Japanese
siegel material included at first no calibres above 15 cm. It was only after two months of the attack that 28-cm. mortars were brought up. Of these the Japanese brought 18 pieces into action, and their projectiles broke through the 1-metre concrete of the permanent forts. But even so the artillery played a secondary rôle. Under these conditions the moral of the defence was bound to be excellent, and the fortress was taken by Nogi only after sapping, mining and very heavy sacrifice of life.

At Verdun the Germans used the same calibres and somewhat the same methods of attack as at Antwerp. The bombardment was to annihilate the defences, and in fact the progress made during the first days was considerable. If they failed in their undertaking it was because the French promptly brought up a great quantity of artillery and established a regular system of reliefs for the troops in line;1 because the broken ground on the banks of the Meuse was favourable to the defence; because the forts had been strengthened by reinforced concrete (some of them, notably Fort Vacheravaulle, were entirely of reinforced concrete), and because the nature of the soil allowed the garrison to dig themselves into shelters, proof against even the 42-cm., right under the houses of the villages. In contrast to these conditions the fortress of Antwerp was built on a uniformly flat site, with water only three feet below the surface. This made it necessary to build all the fortifications above ground and to forego the advantage of deep shelter. The forts were of simple concrete, proof to 21-cm. shells at most. The whole Belgian army was in the line from the outset without hope of reinforcements, fresh artillery, or relief. Added to this, the army, which had at all costs to avoid being surrounded in the fortress, had a vulnerable flank.

It will be seen, therefore, that Antwerp, Fort Arthur and Verdun represent absolutely distinct military situations.

German Occupation: Reconstruction of the Fortress.—Once masters of Liège and Namur, the Germans had lost no time in repairing all the works. They restored the concrete works to their original thickness and filled up all fissures and craters. At Namur most of the cupolas were replaced, but at Liège on the contrary they removed all guns and even numerous armour parts, and proceeded to organize the forts exclusively for infantry and machine-guns. The mechanical and telephonic installations and the ventilation system were improved.2 Door and window apertures were made smaller and a great number of the latter walled up.

At Antwerp, as at Liège, the Germans converted the forts into improvised barracks, facing the city with the defences already applied at Metz.3 They restored the earthworks of the forts, but did not as a rule reconstruct the chambers destroyed by bombardment. Chambers not taken into use were walled up. In the interval they filled up the shell holes with every gun, being allowed none.

On the north front (Blavesveld-Bornheim and the left bank of the Scheldt) the existing trenches were consolidated and formed into two lines joining the gorges of the permanent works. A considerable number of the concrete shelters also were built here for machine-guns or observers, and some for flanking guns. On the north front, facing Holland, from the Lower Scheldt to Fort Schooten, the Germans took pains to maintain in good order the old permanent forts and the interval trenches. The latter were made into a continuous system, generally double, with communication trenches, and concrete shelters and posts. In front were two continuous belts of wire. The flanking was ensured by the traditional batteries of the repaired works and by concrete-machine-gun emplacements. This line was prolonged by an analogous organization, facing north, all along the Turnhout canal and the Oost-Vlaardingen.

The defence system of the river as organized by the Germans consisted of the following elements (all save the last-named on the right bank): Sainttéléi gun-pair (four emplacements for railway guns on pivoted platforms, two for two for two 17-cm. guns near the platforms were reinforced concrete shelters for ammunition and personnel); Blauwensg barrier (12 12-cm. guns in separate reinforced concrete shelters); Lille battery (15 15-cm. guns without concrete protection); Liensinkhout battery (two 12-cm. gun concrete shelters); Ste. Marie battery (six 24-cm. guns in casemates).

1 On Feb. 21 1916 there were in the Verdun system 11 divisions. By July 1, 547 other divisions had done duty in the line, making a total of 65.3. Of this total on an average about 27 were present at any one time.

2 Belgian and German accounts of the siege of Antwerp concur in noting the inadequate ventilation of the forts and the effects of this on their resisting power.

(C. F. A.)
Franco-British Convention of Dec. 23, 1920, affect it (see Syria). The limits of the various independent states of the peninsula, with the exception of the N. boundary of the Aden protectorate, all remain equally undefined. A natural frontier on the N. runs in an irregular curve from Akaba ('Aqaba) first N.E. and then S.E. to the Persian Gulf, following the fringe of cultivation, which fluctuates according as the nomadic or sedentary population is the stronger. This line excludes Kerak, but leaves the transition area of the Hamad or Syrian Desert within Arabia, to which, both physically and ethnographically, it seems to belong.

Topography.—Up to 1914, even the best knowledge of Arabia was sketchy, but considerable advance has since been made by the discoveries of recent travellers and as a result, direct or indirect, of war operations. The progress to be noted falls under three main heads: new light has been thrown on the drainage of the peninsula; the positions of a number of places, previously very imperfectly known or only guessed at, have been accurately fixed; and a vast amount of topographic and ethnographic detail has been accumulated.

The compilation of the map of Arabia on the million scale has kept pace with discovery. For this purpose, the route traverse in northern and central Arabia from Huber's Journal, extending over 3,000 m., was replotted on a large scale and formed a groundwork on which to place the more hurried surveys of Wallin, Palgrave, Doughty, etc. All the labours of recent travellers, starting with Leachman (1916), and ending with Bell (1914), were reconsidered from the originals and adjusted with due regard to the proportionate value of each, while the information collected by Col. Lawrence during the World War and the surveys of Philby were incorporated. The work of compilation was undertaken by D. Carruthers in 1914 and in 1921 was still in progress. Provisional sheets covering the northern half of the country had already been issued.

The course of the main watershed of Arabia can now be traced with general accuracy. Prolonged northward from the highlands of Yemen and Asir, it passes inland between Taif and Wadi Namar and runs E.—n. W., as was previously supposed—of the Hejaz railway through the Khobzah valley, or lava outcrop. Perhaps some of the higher peaks of the 'Amerdih ridge overlap it.

The main drainage basin of the so-called western slope of Arabia, previously thought to have its head-waters in the vicinity of Medina, at about lat. 24° N., in all probability has its source in W. 'Aqaid at lat. 3° N., 27° S., thus giving it a total length of 700 to 800 m., including windings. The 'Aqaid rises S.W. of Taif, passes well to the E. of W. and Medina and is said to take the name W. Shabha between these two towns. Some doubt remains whether the Shabha discharges wholly into the Hamdih just N. of Medina, or whether it also forms a tributary eastward in W. Rumma (Rima). Wadi 'Ais, coming from the N., and W. jizil from the S., and joining W. Hamdih in the plain of jurf are its two main affluents, and their courses, together with the middle reaches of the Hamdih, have been explored in great part and mapped.

Much new information has been obtained as to the drainage of the long eastern slope—effected mainly by the great wadi systems of the Dawasir, Sahaba and Rumma (naming from S. to N.). The town of Dam, in W. Dawasir, central Arabia, previously mapped near lat. 23° N., has had its position definitely fixed in lat. 20° 27' N. and long. 44° 40' E. The direction of the course of W. Dawasir, a matter long in dispute, proves to be E., towards the Ruba' el Khali, or Great Southern Desert, and not N.E. as the old maps show. The point of junction of the important Aqaid—Ruma—Rana and Taif—Ruma—is in all probability in the plain of Hanifa, about 50 m. N.W. of Dam. As to W. Sahaba, which has a practical monopoly of the surface-waters of the central mass of Arabia and the drainage of which trends to the sea at the southern end of El Qatar, it was found to have its remotest head-water in W. Sirra, in the very heart of the peninsula. Under the name of W. Birk, the Sirra breaks through the Tuwaq plateau and, turning W., reaches the S. of Hanifa some 60 m. S.E. of Riyadh (lat. 24° 27' N., long. 48° 41' E.). W. Hanifa ultimately falls into the Sahara, but the latter probably carries no surface-water, at any time, farther than the western fringe of the Dahana, about long. 48° E. Wadi Subah, rising somewhere in lat. 22° N., is probably the most southern tributary of W. Rumma.
Northern Arabia.—In 1910, Lt.-Col. G. E. Leechman, out from the British Army for Hall of Fame War (1914-18) and later performing Leina, he had to return to Samawa. Again, in 1912, he left Damascus intending to cross Arabia from N. to S. He got as far as Riyadh by way of Ha'il, Leina, and Bodeila, but the emir of Nejd informed him that he was not to proceed any further. He was doubtless inspired by the usual sand-belts of the region, and was taken in; he had to return to Ha'il, where he was interned, as no communication between Syria and Iraq via the oasis of Jaff was obtained, that result that is obtainable at regular intervals along it. He was first among Europeans to visit the remarkable wells of Leina, of which there are several hundred, spread over an area of 50-60 sq. m.; and is the only European who has made any record of a journey from J. Shammar to Suq Shuyukh. His travels were equally important politically, for he laid the foundations of a great friendship between the emir of Nejd and St. John. He was released, discharging his duties, for the first time, was able to describe

Jebel Tuwaq, the salient physical feature of central Arabia, was for a long time considered as very important. For a long time, some 500 m. above the average level of the surrounding desert, it was considered as a barrier between the Nejd and the Dhaif, and the Dhaif and the Dariyah. It is a feature of the Sea of Khor and Hadramaut, and has been known for a long time. It is a feature of the Sea of Khor and Hadramaut, and has been known for a long time. It is a feature of the Sea of Khor and Hadramaut, and has been known for a long time.
this hut village. In Yemen, in 1909, a considerable amount of survey work was done by M. A. Beneyton, a French engineer, for a proposed railway from Hodeida to San'a and 'Amran (see below) and, as a result, much unexplored territory was mapped on a scale of 1:250,000. G. Wyman Bury went from Hodeida to San'a in 1912, and made a long stay at Menakha in the same year. He has thrown more light than perhaps any recent traveller on the toponymy and economics of Yemen. A. Waddell visited San'a in 1911, and gave the best description of the city since Manzoni, 1884. He found the population reduced to 18,000 as compared with Hadda's estimate of 50,000 in 1873. The decline in numbers and the commercial depression prevalent in Yemen may be attributed largely to the lawlessness of the intractable Zaranik and Qatun tribes who occupy the country between the highlands and the Red Sea.

**Aden Protectorate and Hadhramaut.**—There is little new information regarding these districts. Bury, in 1911, described the penetration of the Kaur watershed (alt. 7,000 ft.), N. of the Yafa' Fatih country. He visited Yaboom (pop. 4,000), the capital of the Upper 'Aulagi, situated in a plain producing cotton and indigo, and carrying on an industry in cotton fabrics, and got as far as Behnan, 110 m. inland of Shograh and almost in touch with Manzbi.

**The Red Sea Coast.**—The naval patrol during the World War added much to knowledge of the very intricate coastline from Akaha to Aden. The triple coral reef fringing it had kept this coast almost inviolate, but the very numerous openings through the reefs are now known and have been charted.

**Political History.**—Before the World War, the Porte claimed control of Arabia in its entirety as rightfully part of the Ottoman Empire in virtue of the Sultan's authority as caliph. In actual fact, most of the peninsula was under a number of independent native rulers, only some of whom acknowledged Ottoman influence, and that to a limited degree, while others were under British protection. Effectual Turkish jurisdiction was confined, in the Hejaz, to the two Holy Cities, their ports, and the line of railway; in Asir, to one or two small ports and the inland districts of Ihiba and Muballit; and, in Yemen, to certain garrisoned towns in the interior and to the ports of Hodeida and Mocha and connecting roads. The Hejaz railway, built nominally for the benefit of pilgrims to Mecca but in reality to increase the Ottoman hold on Arabia, did not fulfill political hopes, partly because it served not more than a third of the territory that the Turks claimed and partly because of the immense difficulties of its maintenance and working; and it brought about little or no economic development in the peninsula.

The World War marked the passing of Turkish control from the whole of Arabia and, at the opening of 1921, there existed the following principal autonomous elements: the kingdom of Hejaz; the emirate of Nejd and El Has; the emirate of Jebel Shammar; the Principality of Sabia in Asir; the Sultanate of Yemen; the sheikhdoms of Kuwait, of Bahrein Is., and of El Qatar; the Trucial Oman; the Sultanate of Muscat in Oman; the Ka'aiti and Kathiri sultanates of Hadhramaut; and the autonomous tribes under treaty with Aden. But this list does not exhaust the autonomous, for there are many tribal communities—settled, half-settled and nomadic—which owe allegiance to none but their own local chiefs, such as certain sections of the Anaza and Muntefiq in the N. and the Zaranik and Yam in the S. The parcelling of the peninsula among so many separate communities is largely the result of peculiar geographical conditions which have rendered such a segmentation natural and increased the number of vassal, or in cases or wadis; and it is only by virtue of some peculiar source of wealth, some common spiritual ideal or cohesive external support that larger territorial dominions have been established.

**The Hejaz.**—War with Turkey entailed on Great Britain and her Allies certain dangers in Arabia owing to the efforts made by the Central Powers, through the Porte, to arouse Moslems to a *jihad* or Holy War. Whether this result followed or not, there was every likelihood that the Turks would try to hinder the free use of the sea route to the East and, if kept in connecting roads, to cut off communication with the hinterland, further the advance of the Allies in East Africa and the Farther East would be dangerously accessible to the enemy. Great Britain therefore turned to the sheikh of Mecca (Hussein Ibn 'Ali), believing that the metropolitan position of the Holy Cities of Islam and the venerated lineage of the sheikh would make very effective his refusal to countenance a *jihad*, while if he declared against the Turks, the geographical position of the Hejaz would make the materialization of the other dangers improbable. Sheriff Husein was, known to desire the emancipation of the Meccan emirate.

Under the Ottoman régime, the Hejaz was a vilayet, with a vahi resident at Mecca. Nominallv, it included all the area S. of Ma'an to Liath, and was subject to taxation; but the cities of Mecca and Medina were not only tax free but were in receipt of subsidies from the Ottoman treasury, as were also certain Harb sheikhs who were able to interfere with the passage of pilgrims or if in the railway tracks. The whole vilayet was exempt from services in the Turkish army and succcessfully resisted an attempt to impose conscription in 1914. The Porte maintained forces in the Hejaz, the normal garrison being about 7,000.

Side by side with this foreign government, existed the authority of the sheif or emir of Mecca, enjoying extra-territorial independence at Mecca and Taif with the right to keep official representatives to watch over his interests at Medina, Jidda and elsewhere. The emir was able, at need, to call out considerable levies of Hejaz and other Bedouins and, by so doing, under semblance of helping the Turks, successive emirs not only made a fortune in touch with the Porte but inspired it with a wholesome respect and, at the same time, engaged a fighting force which could be used some day for their own ends.

Sheriff Husein was nominated to the emirate in 1908, as a man of pacific character, likely to serve the Porte's purpose. In 1910 he took up arms for the Turks against the Asir revolt under Idrisi. In the same year he extended his influence over a part of the territory of the emir of Nejd in central Arabia. But in 1913 he began to pursue an active anti-Ottoman policy, ostensibly opposing the extension to Mecca of the Hejaz railway and supporting the Harb tribesmen in their resistance to this and other Turkish projects; and he organized the Hejaz tribes acknowledging his authority, with a view to insurrection. He reconciled himself with Idrisi and tried (without success) to get the support of the imam of Yemen in his anti-Ottoman aim; and, in 1915, he sent 'Alkalla, his second son, to bring about a truce between the emirs of Nejd and J. Shammar.

In the summer of 1915, Sheriff Husein declared his desire for a revolt to the Allies, who thereupon agreed to support him with money, munitions and supplies. A long period of inaction followed, however, and it was not until June 1916 that the revolt actually broke out. After the loss of Jidda, Mecca and Taif by the Turks, Husein proclaimed himself independent of Ottoman rule June 1916. To explain his attitude to the Moslem world, he issued a proclamation (Aug. 1916) setting out a number of indications against the Committee of Union and Progress; and, finding that the Ottoman Government was unable to spare any large force to oppose his aims, he was formally proclaimed "Sultan of the Arabs" in Oct., a large number of chiefs assembling in Mecca to support him. He relinquished this title for that of "King of the Hejaz" in Dec., and was so recognized by the Governments of Great Britain, France and Italy. In 1917, Wej and Akaha being lost by the Turks, the newly established kingdom was able to maintain its separate existence, and the emir was left, except in name, a vassal of the Emir of Mecca. By the Treaty of Armistice, the Turks refused to surrender Medina until Jan. 1916. The Hejaz was represented at the Peace Conference by the Emir Faisal, King Husein's third son, and the state was admitted a member of the League of Nations in 1920. By the treaty of peace with Turkey, that country renounced all rights and titles to the Arabian peninsula and the King of the Hejaz undertook to ensure free and easy access of all Moslems to the holy places of Mecca and Medina. The treaty had not, however, been ratified by the Hejaz at the beginning of 1921.

King Husein maintained friendly, but formal, relations with the emir of Nejd during the World War; but, in 1920 and the early part of 1924, there was frequent friction between them over the debatable border at Khurma in the neighbourhood of Taif. A battle at Turaba, near Taif, in May 1919, resulted in a loss of 4,500 men to the Hejaz army; but the emir of Nejd did not follow up his advantage. In June 1920, relations between the dis-
patents were reported to be more friendly; but the frontier still remained undefined in 1921.

The Central Emirates.—The emirate of Nejd, capital Riyadh, and that of Jebel Shammar to the N., capital Halli, comprise all the country between the main northern and southern deserts of Arabia. Between the two emirates lies the oases of Qasim and Sedeir, the overlordship of which has been in dispute for more than two generations. The two emirates control, more or less effectively, all the peoples both settled and nomadic of central Arabia, and the authority of the emir of Nejd extends to El Hasa on the E. and to certain tribes of the Asir border and Wadi Dawasir on the W. and S. Wahabism, or its more modern manifestation the Ahwani movement, supplies the moral basis of the power of the emirate of Nejd, while the settled nature of the population is its material basis. The emirate of J. Shammar, on the other hand, grew out of the desert power of a great nomadic society accustomed to maintain a group of permanent villages and hamlets around J. Aja and Selma, which served as rallying places and as market centres. The Shammar emirate, while inferior to its rival in wealth and settled population and lacking its religious tie, owes its strength to the unity existing between its oasis folk and the tribes of the surrounding regions, to the patriarchal tie binding them, and to the stimulus of the steppe desert upon its life.

Nejd (see 10.331) comprises all the oasis groups situated about or on the Tuwayq plateau, extending well over 500 m. from N. to S., and is directly or indirectly under the rule of Ibn Sa'ud of Riyadh. In addition, the emir lays claim to El Hasa, on the Persian Gulf between lat. 24° and 26° N. He drove the Turks from this district—which they had occupied as a sanjan of Busra since 1877—in May 1913, and was acknowledged by the Porte as sâli of Nejd and El Hasa. He, however, effectively occupies only the HofUF group of oases, with the ports of Qaisif and 'Otair. In 1914, Ibn Sa'ud entered into relations with the British Government—Capt. Shakespear being appointed political officer in Riyadh—and proved an unswerving ally throughout the World War. He declared himself definitely against Ibn Rashid, emir of J. Shammar, who had allied himself with the Turks. He fought a drawn battle with Ibn Rashid at Mejma' in 1915, the main point in dispute being the ownership of Qasim with the towns of 'Aneiza and Boreida; it was in this battle that Captain Shakespear was killed. His attitude towards the Hejaz, while war lasted, was friendly but formal. By 1918, after intermittent and generally successful campaigns against the emir of J. Shammar, Ibn Sa'ud had established his supremacy in central Arabia, including Qasim and Sedeir. His relations with the King of the Hejaz, in 1919—20, became less cordial, frequent disputes having arisen over the frontier question. He is believed to have steadfastly refused either spiritual or temporal allegiance to King Husain. Early in the summer of 1920, Ibn Sa'ud turned his attention to E. Arabia and instigated an attack on Kuwait, which port he is said to covet. Several actions took place but without definite result, and subsequently efforts were made on the part of the British Government to bring about a territorial agreement between the emir and the sheikhs of Kuwait.

Before the World War, the authority of Ibn Rashid was supreme in the group of oases about J. Aja and J. Selma; in the steppes N. of Qasim, from the Hejaz border (including the oasis of Teima) almost to Kuwait; and in the oasis of Jauf el Ammar. On the N. and E., the southern Nejdah and the Dahana formed a neutral zone between his territory and that of the nomad tribes between the Hejaz and Sa'ud. Ibn Rashid's attitude in the World War was consistently pro-Turkish, though relations between him and the adherents of the Committee of Union and Progress were probably never cordial. The comparative ease with which the Turks could reach Hail, from either the Hejaz railway (at Mu'adhliham) or from Samawa and Nejef, contributed towards making him sensitive to Ottoman pressure. He was reported to have supplied the Turks with large numbers of camels, especially for the expedition against Egypt in 1915—6. As the World War proceeded, his power diminished, both territorially and economically.

While Ibn Sa'ud was fighting the Turks in El Hasa (1913), Ibn Rashid was able to maintain his position; but, in 1915, an attempt on his part to overrun Qasim and Sedeir resulted in the loss of the towns of 'Aneiza and Boreida, and they were placed under tribute to Ibn Sa'ud. The oasis of Jauf, on the caravan road from Damascus to Hail, was seized in 1910 by the Rweida tribe of the Anaza under Nuri esh Sha'lan, one of the most powerful and anti-Turkish of the nomad chiefs. Nuri had shown himself a successful rival of Ibn Rashid, for, in spite of determined attempts on the part of the latter to regain the oasis (notably in 1914), he was not able to reestablish his authority in Jauf. The important oasis of Teima, also, reverted to the Hejaz in 1917. In the same year Ibn Rashid went to reside at Medain Saleh and, for a year, did not set foot in his capital. In May 1920, his murder was reported.

Asir.—The limits of this district are indeterminate, but broadly it comprises the country lying between the territory under the jurisdiction of the King of the Hejaz—who claims control of the Tihama down to Qunfuda—and that of the imam of Yemen. Its eastern limit is contiguous with Nejd. There is a strong political and social distinction between the people of the Tihama lowlands and those of the highlands which constitute Asir proper; and there is no part of Arabia where the tribal elements are so sharply defined and their boundaries less changeable. Settled tribes are the predominant element in Asir, and the physical conditions favour the pursuit of agriculture sufficiently to render nomadism unnecessary. In religion, practically all the tribes are Shaefi Sunnites; Wahabism has a few adherents and its tenets are regarded sympathetically all over the district; but everywhere there is a strong antipathy to Zayidis.

Asir cannot be regarded as a political entity. In 1914, it fell into four parts—sections acknowledging the Turks, the Idrisi of Abu 'Arish, and the sherif of Mecca respectively, and small groups of nomad tribes on the E. who recognized no authority. The Turks claimed the whole of Asir as the northern section of the vilayet of Yemen, but never succeeded in subduing the country and, in reality, they only precariously held the inland towns and immediate surroundings of Ibbah and Muhall and the port of Quadfa, all of which they garrisoned. The authority of the Idrisi was restricted to a strip of the Tihama some 80 m. long and extending about 40 m. inland to the scarp of highland Asir, with Sabia as capital and Jeizan and Medi as ports. The influence of the sherif of Mecca was mostly confined to the Ghamid and Beni Shihir tribes on the inland side of the ridge.

Interest in Asir, during the World War, was centred on the Idrisi, Scywyid Mohammed. His aim throughout was to rid the district of Turkish control and to extend his own influence. By 1916, he had much reduced the Ottoman hold and, in 1917, subsidized and supplied by the Italians during their war with Turkey, he consolidated his position. In 1914, failing to obtain sufficient recognition of his power from the Turks, he declared himself definitely against them. He concluded an agreement with the British resident at Aden in May 1915, and was supplied by the Allies with material. He raised part of the Zaranik tribe and took the field, ostensibly against the Turks, with a nominal following of some 12,000 men and overran the Tihama of Yemen, but failed to capture Loheia, one of his main objectives.

In reality, his support of the Allies was not of a very positive character, as he was in constant fear of attack by the imam of Yemen; and the Turks held Ibbah and Muhall, their stronghold in the interior, until the Armistice. He kept on good terms all the time with the King of the Hejaz. The actual extent of the Turkish control was a matter of doubt; but his attitude towards the imam of Yemen continued to be hostile, though there had been short periods of truce between them. In Feb., information reached England that Idrisi forces had occupied Hodeida.

Yemen.—As in Asir, the social contrast between the highlands and lowlands is very marked, being the outcome of religious and racial differences reinforced by strongly contrasted geographical conditions. Broadly speaking, the central highland population is Zaidite (Shihah) and accepts the authority of the imam, whereas
against the Sultan, for which this control was made part pretext, took a serious form in 1913 and necessitated the bombardment of the ports of Qurnat and Barka, and the bombardment of Butt el Fejej near Muscat. The rebels attacked in strength in Jan. 1915, but met with defeat, which relieved the situation. The disaffected tribes continue to dominate the interior, and the author- ity of the Sultan, rather than that of the Imam, is recognized by the tribes.

Trucial Oman, formerly known as the Pirate Coast, extends for over 300 m. from El Qatar almost to Ras Musandam, and takes its name from the truce established in 1853 between the fiverecognized sheikhdoms of the district of Abu Dhabi, Dibai, Sur, 'Ajman and Um el Quwain. The position of the respective sheikdoms is regulated by an agreement which, in 1892, placed all external relations under British control and made the Sultan responsible for their reception from aggression. The sheikdoms are very unequal in importance—those of Sharja and Abu Dhabi are the most distinct territorially. The sheik of Sharja claims to be paramount among the Trucial Oman, and was recognized by Great Britain in 1915, and not recognized by Great Britain. An Arab political agent resides at Sharja.

El Qatar.—The sheikdom of El Qatar comprises the peninsula of that name on the Arabian coast E. of Bahrein, of which latter it was formerly regarded as a dependency. Turkish control in El Qatar ceased in 1913, when the emir of Nejd drove the Turks from El Haza, and the sheik, Abdulla ibn Jasim came into power in the same year. He maintained friendly relations with Britain and kept on good terms with the emir of Nejd.

Bahrein (see 5.312) consists of an archipelago, of which Bahrein is the most important, and in the R. over that part of Bahrein I. adjacent to the port of Manama and over Mulharraq I.: his authority over the remaining islands is little more than nominal. He agreed by treaty, in return for a subsidy and proprietary rights on the luxury goods of his territory (forbidden to be sold to or by British subjects), to be relieved of his personal responsibility for the conduct of his territories. The island of Bahrain is about 7 miles long, and 3 wide, and contains a town of the same name. It is the principal harbour of the Gulf.

Kuwait.—The Sultan of Kuwait (see 15.996), Salim, son of Mubarak, who succeeded his brother Jabir in 1917, claimed jurisdiction over 200 m. of territory from El Haza almost to the head of the Persian Gulf, and ruled nominally westward to the wells of Haifah, where his district met that of the emir of J. Shammara N.E., and that of Nejd on the S.W. The late Sultan Mubarak formally repudiated all relations with Great Britain on the outbreak of hostilities; but his attitude towards the emir of Nejd was friendly, and it was communicated to the British diplomatic representative at Bushire, that he was stationed at Manama. Throughout the crisis in the pearl industry in 1915, and during the World War, the sheik showed much goodwill to his relations with British officials, and in 1921 and was succeeded by Ahmad ibn Jabir.

On March 1 1921, it was stated in Parliament that matters of policy and administration affecting Arab areas within the British sphere of influence and Aden were transferred to the Colonial Office; but questions regarding the Hejaz remained under the jurisdiction of the Secretary of State for Foreign Affairs. The tendency was for the British Government to rely considerably on officers of the Sudan Civil Service.

Trade. —Arabia produces little for export except pearls, dates, coffee, hides and skins; imports consist almost wholly of manufactured goods. Sheikdoms produce cottons, rice, (beer), tea, and tobacco. Besides Aden only Muscat, Manama and Kuwait carry on any considerable direct and regular trade with the outer world—the first named with Europe mainly, and the others almost exclusively with India and the East; and Arabian trade in general tends to focus more and more on Aden and Manama. The trade of Jidda—depending largely on the pilgrimages, and seasonal in consequence—though considerable, is of a more local nature and is mainly with the Port Said, the Red Sea, and the Persian Gulf, and India at farthest. The trade of Hodeida, near Aden, is the same as that of Aden.

The trade of Hodeida, Jeizan, Mocha, Makalla, and the other smaller ports is almost entirely carried on by sailing craft, though before the World War, Hodeida was also a port of call, at regular intervals, for certain smaller lines of steamers. Commercial enterprise at Arabian ports is mainly in the hands of Indians, especially in Oman, Kuwait, Hodeida, and even at Aden; second to them come Italians, commercially predominant in many of the Red Sea ports (notably Hodeida), German Somaliland and Eritrea offering a convenient base of operations. Prior to the World War, British and Turkish interests were political rather than commercial; neither power had any strong hold on the economic activities of the country, the trade relations between Turkey and the Holy Cities excepted.
The following comparative table gives approximate trade figures (including specie), in thousands of pounds sterling, of the chief ports, in the years just anterior to the World War:

The marked increase at Jezan was due to war operations in Asir; the almost total extinction of trade at Hodeida in 1916-9 and the temporary revival of Mocha, at the expense of Hodeida, to the trade of the Yemen ports, which had fallen off at Jidda in 1915-6 to the temporary blockade of the Hejaz coast just previous to the Arab revolt. There is normally a considerable direct trade between certain Red Sea ports and Egypt (Suez). In 1918, it amounted to about £250,000 of which imports were £225,000, chiefly cotton piece-goods (£157,000), soap, dried beans, sugar and lentils; and exports, chiefly charcoal.

The main item in the trade figures of Jidda is the export of specie amounting in normal times, to well over £1,000,000 annually. As to trade in general commodities, there is always an enormous excess of imports over exports, due largely to the requirements of pilgrims, the Hejaz producing little. In 1917, imports included rice £23,000 (from India); maize, wheat and barley £181,000; cotton-piece-goods £300,000; silk goods and sugar, and, in that year, 287 steam vessels of 616,000 aggregate tonnage entered the port. Exports in the same year did not exceed £50,000 and consisted of skins and hides, wool, henna, gum and mother-of-pearl shells. The number of pilgrims passing through Jidda in 1912 was 83,295.

Midi (Asir), 45 m. S. of Jezan, became a port of some importance during the war. In 1917, the construction of a stone pier for the discharge of cargo was undertaken. Hodeida was formerly the most important of the southern Red Sea ports, but during the past decade its trade has steadily declined. In 1910, imports amounted to £60,000 and exports to £50,000; in 1919, the latter consisting mainly of coffee, hides and skins. The Yemen coffee trade, valued at about £200,000 in 1911-2, has passed almost entirely to Aden, which is the port of the Aden coffee. It is expected that the facilities for handling the Barik and the better facilities there for hugging the barik, and export, in 1921 the port was reported to be almost deserted. The scheme for a new harbour at Khor el Kethib, a good natural inlet 10 m., N. did not materialize.

The Eastern Littoral.—The following comparative table summarizes the value of the trade (including specie) of the chief ports, from 1912-20, the figures being in thousands of pounds sterling:

Muscat is the main trade outlet of Oman. The decline in trade after 1913-4, shown in the table, was due partly to the opening of the Trucial Oman and a free port, partly to the blockade upon the arms traffic in 1914. The import of arms fell from £180,000 to almost nil in the period 1913-5. In 1918-9, 80% of the total trade was with India, 12% with the Arabian countries, and 8% with the Levant. The commercial security of the port was taken over by the Foreign Service and the port tonnage 57,837 cleared the port; the tonnage carried by sailing vessels was 20,149. The most important article of export is dates (£120,000 in 1918-9), of which the better sorts of dry dates go to the New York and Boston markets; of secondary importance are pearls, mother-of-pearl and salt fish, mainly to India. Rice from the chief rice ports was also exported.

Mamana holds a somewhat similar position to Aden as a place of transhipment and centre of distribution for eastern and central Arabia. It is the headquarters of the Persian Gulf pearl industry, in which it is said that 5,000 boats are engaged. The exceptional decrease of exports 1914-6 (see above table) was due to the decline in the pearl trade, which fell in value from about £1,800,000 in 1912-3 to £200,000 in 1915-6, causing great economic stress. In 1919-20 the chief imports were rice £406,000, piece-goods £337,000, coffee £32,000, and sugar £33,000; exports, pearls £729,000 (131,000 in 1918 and £702,000 in 1919), rice £23,000, pearl oyster goods £8,000, and salt £8,000. 75% of the trade was with India and 25% with other ports of the Persian Gulf; and 56 steam vessels of 111,244 aggregate tonnage entered, of which 109,073 was British.

At Kuwait the principal exports (in 1919-20) were cotton piece-goods £381,000, rice £171,000, coffee £21,000, sugar and tea; and exports, rice £58,000 and ghi £14,000. In the same year, 47 steam vessels of 89,909 aggregate tonnage entered; India furnished 82% of the total imports, and 70% of the exports for other Arabian ports. Pearl boats valued at £27,000 were built in 1912-3.

The Interior.—The principal market centres of the interior of Arabia are: Teima and Khobair (Hejaz), Muhail and Khamis Mushait (Asir); San'a (Yemen); Makhlal (Norjan); Lahej (Aden hinterland); Shibam and Hauta (Hadramaut); Semail, Kostaq and Nisran (Hijaz); Riyadh, Badr and Hai (Hejaz); Hofuf (El Hasa). Trade at these centres consists in the collection of the small surplus native agricultural products and in the distribution of manufactured articles and foodstuffs brought in from the coast.

Communications.—With the exception of the Hejaz line, Arabia was still without railways at the end of 1920. Two extensions of the Hejaz line were projected: (1) Medina-Mecca, to Jidda; and (2) Ma'an-Akaba. The first formed part of the original plan of the distance direct being projected to fall under £1,000,000. An alternative route, via Rabugh, was also considered and construction was begun at both Medina and Rabugh, but was abandoned. The Ma'an-Akaba scheme did not go beyond the preliminary survey stage. In 1911, a survey of a railway from Mecca to Jidda was made by the Turks, but construction was postponed. In 1909, French engineers surveyed for a railway which the Turkish Government proposed to build from Hodeida to San'a and 'Amran. Alternative routes were considered—one direct via Bajil and Hafia, and the other making a detour through Zebid, Ta'iz and Yerim. As a preliminary, a French syndicate constructed a narrow-gauge 5-6 m. of. railway from Hodeida and proposed new harbour at Khor el Ketib, about 10 m. to the north. The work and all material and plant (including several locomotives) were destroyed in the Italian bombardment of Hodeida, in 1912. In 1918-9 a metre-gauge military line was extended from Sheikh Othman to a few miles beyond Lahej, a total distance of 25 m. from Aden; when not required for military purposes it is available for ordinary transport.

There are no made roads of any considerable length in Arabia, except one of 173 m. from Hodeida to San'a; but sections of the old caravan tracks were adapted during the World War for rough motor service, e.g., the road from Jidda to Mecca and from Akaba to Ma'an. For purposes of trade, the old caravan routes have still to serve. The only route of trans- peninsular character is that from Zobeir to Boreida (370 m.), Mecca (470 m.) and Jidda (55 m.); total, 915 m. For the passage of trade as well as pilgrims, no other caravan route in Arabia compares with it in importance.

The lines of telegraph are: Jidda—Mecca; Jidda—Rabugh—Medina; Hodeida—San'a; Hodeida—Mocha—Sheikh Sleil; Hodeida—Loheba—Mi'di; and Mocha—Ta'iz—Yerim—San'a. In the chief ports there is an electric light service.
Industries.—Camel-rearing is mostly in the hands of the Anaza in the N., the Qashan and Shammar in the centre, and the 'Ajman and Muteir in the E.; but the herds of the first-named tribe far outnumber those of any other. The centre of the camel trade is in Damascus (where almost all the capital is supplied) and to a less extent in Baghdad. In normal times, the chief tribes are said to possess 720,000 head, but during the World War herds were much depleted. Only the surplus, possibly numbering 45,000 per annum, and those not the best, are sold. A little horse-breeding is carried on by the emir of Nejd and by the Shafrah tribe. An attempt to send small export to Mesopotamia and Syria. Considerable numbers of the white, large-boned breeds of asses of El Hasa are sent to Egypt. The fisheries of Arabia, other than pearl, are valuable for the supply of local needs and are capable of development. The salting of fish is an industry at most coast towns, but more particularly those of the Red Sea and Oman; considerable quantities are sent into the interior. During the war operations, some attention was paid incidentally to the study of the Farsan pearl industry and to the possibilities of its development. The rock salt quarries of Sulfi, opposite Kamaran I., were worked under the control of the Ottoman debt and 205,000 tons of salt were exported to India and the Straits Settlements in 1909. Just prior to the World War an English company was working the quarries; in 1920, operations had ceased for the time being.

ARABI PASHA (6.8.1939–1917), Egyptian soldier and revolutionary leader (see 2.298), died at Cairo Sept. 18 1917.

ABER, EDWARD (1836–1912), English man of letters (see 3.323), was killed in a taxicab accident in London Nov. 23 1912.

ARBITRATION AND CONCILIATION [LABOUR] (see 2.313).—Subsequently to 1910, many countries found it necessary to revise their position in regard to arbitration and conciliation in industrial disputes. The growing organization of workers in trade unions which was a marked feature of the last generation rapidly increased as a result of the demand for labour occasioned by the World War; and the feelings aroused by these developments, the workers making demands on behalf of workers in all countries, which the strong economic position of the workers enabled them to enforce. To war itself in certain instances necessitated exceptional measures in order that the output of munitions of war might not be hindered by strikes and lockouts. Further, the development of industry has been towards more and more specialization and a still closer inter-relation of industry, so that the effects of strikes and lockouts extend far beyond those immediately concerned and may have most disastrous effects on the public. For this reason the state is forced, in the interests of the community, to take cognizance of trade disputes.

UNITED KINGDOM

The position in the United Kingdom, at the outbreak of the World War, was that questions affecting rates of wages and conditions of employment were settled normally by discussion between the parties concerned. During the course of half a century, voluntary conciliation boards, standing joint committees or corresponding procedure had been established in all well-organized industries and this procedure was instrumental in settling large numbers of disputes. In certain important industries, e.g. agriculture and transport, the workpeople and employers were not sufficiently organized in associations to render such permanent machinery practicable. The statutory powers of intervention in labour disputes held by the Government were in return used only exceptionally. The Act, 1864, an Arbitration Act, was framed upon a purely voluntary basis. A connecting link between the activities of the conciliation boards and those of the Government in the settlement of labour disputes was the provision in the regulations governing the procedure of a number of boards for the reference of differences to arbitration under the auspices of the appropriate Government department (since 1916 the Ministry of Labour), and further by the policy of the department in not intervening in a dispute until the parties had exhausted their efforts to bring about an amicable settlement.

During the period immediately following the passing of the Conciliation Act, comparatively little use was made of the procedure of the Act, but the three years immediately preceding the war were years of very marked industrial unrest in the United Kingdom and there was a corresponding increase in the use made of the provisions of the Act. Serious consideration was given by the Government to the question of strengthening their powers in relation to labour disputes, but up to the outbreak of war no steps had been taken to formulate legislative proposals. In this connection, reference may be made to the report of Sir George (afterwards Lord) Askwith of Dec. 1912, on the Industrial Disputes Investigation Act of Canada (Cd. 6063), and the report of the Industrial Council on Industrial Agreements (Cd. 6075).

Committee on Production.—The needs of the war and the abnormal conditions arising therefrom made both necessary and possible much stronger Government action in regard to stoppages of work. The outburst of patriotic feeling which followed the declaration of war resulted in employers and workpeople voluntarily bringing to a close the existing and pending disputes, but the economic conditions resulting from the war soon produced a fresh series of labour difficulties. In Feb. 1915, the Committee on Production, consisting of Sir George Askwith, Sir Francis Hopwood (Lord Southborough) and Sir George Osborn, representing the Board of Trade, the Board of Agriculture and the War Office respectively, was established by the Government to enquire into and report as to the best steps to be taken to ensure that the productive power of employees in engineering and ship-building establishments working for Government purposes should be made fully available, so as to meet the needs of the nation in the present emergency.” With the establishment of the Ministry of Munitions, the functions of the Committee in relation to production were absorbed by that Ministry; but in the meantime the Committee had developed, as a result of the acceptance by the Government of one of its earlier recommendations on the subject of stoppages of work, into an arbitration tribunal. It had no statutory position until the passing of the first Munitions of War Act in July 1915, but it quickly developed into the principal arbitration tribunal for the settlement of labour disputes and attained remarkable success. In 1917 the
Committee was reorganized, representatives of employers and workpeople being added, to sit with the independent chairman. The Committee ceased to exist at the termination of the war when its place was taken by the Interim Court of Arbitration established under the Wages (Temporary Regulation) Act. During its period of existence, it issued over 3,750 awards covering most of the important industries in the country and dealing with all kinds of questions of wages and working conditions. In particular, reference may be made to the agreements negotiated, first in the engineering and allied trades and later in a large number of other trades, whereby the associations of employers and workpeople agreed to suspend existing agreements for the determination of general wages questions and to refer to the Committee on Production every four months the determination of the question what general alteration of wages, if any, was warranted by the abnormal conditions then existing and due to the war, with further power to determine special district cases.

The next important development after the institution of the Committee on Production in Feb. 1915, was the "Treasury Agreement" on the subject of the acceleration of output on Government work, negotiated between the Government and the principal trade-unions in March 1915. The Government's main proposals embodied in the Agreement were on the one hand to limit profits and on the other to prevent stoppages of work owing to trade disputes, and to secure the suspension during the war of trade-union restrictions on output. Although this agreement marked a definite stage of advance, real progress was not made until the Government embodied their proposals in the Munitions of War Act, 1915. This Act was subsequently strengthened by two further Munitions of War Acts in 1916 and 1917.

Munitions Acts.—Under the Munitions of War Acts, a stoppage of work arising out of a difference on or in connexion with munitions work (which expression was given a very wide interpretation as the result of decisions of the High Court) became illegal unless the difference had been reported to the Board of Trade (subsequently to the Ministry of Labour) and had not, within 21 days from the date of the report, been referred for settlement. The compulsory arbitration thus introduced by the Acts was necessarily accompanied by the statutory enforcement of awards issued thereunder. For this purpose the existing forms of arbitration tribunal were utilized, viz., (1) Committee on Production, (2) conciliation arbitrator, (3) ad hoc boards of arbitration, consisting of an independent chairman, an employers' representative and a labour representative. This last form of tribunal had been introduced in 1908 for appointments under the Conciliation Act in order to meet any objection on the part of Labour that, however fair a single arbitrator might be, he could better determine the matters at issue if there were associated with him persons directly acquainted with the point of view of employers and workpeople respectively. The Act of 1915 left it to the option of the Board of Trade to refer any difference reported under the Act to arbitration; the Amending Act of 1916 required the Board of Trade to refer such a difference if satisfied that it was bona fide. Although the definition of "munitions work" under the Acts was very wide, it did not include some very important industries such as mining, transport and agriculture, but a further provision of the 1915 Act enabled the parts of the Act relative to the prohibition of strikes and lockouts and compulsory arbitration to be applied to work of any description (in addition to munitions work) by His Majesty by proclamation, and this course was adopted in certain instances (notably South Wales and the Lancashire coalfields). When the war ended, the Arbitration Tribunals of Liverpool, London and the South of England were transferred to the Board of Trade. It may further be noted that the Munitions of War Acts contained no prohibition of incitement to strike. Consideration was given to this aspect of the problem and in Nov. 1915 the Defence of the Realm Regulation No. 42 was amended by the addition of the words in italics as indicated below:

> If any person attempts to cause mutiny, sedition or disaffection among any of His Majesty's forces or among the civil population, or to impede or restrict the production, repair or transport of war material or any other work necessary for the prosecution of the war, he shall be guilty of an offence against these Regulations.

The Acts also authorized the Minister of Munitions inter alia to issue orders determining the rates of wages of particular classes of workpeople and a considerable number of orders were issued with regard to the rates of remuneration of women and girls. Other orders which had widespread effects were the orders made in Nov. 1915, giving a bonus of 12½% on earnings to skilled time workers in engineering establishments and in shipyards, with a view to attempting to meet difficulties which had arisen owing to the altered relation between the earnings of skilled time workers and the unskilled and semi-skilled men on piece work. Three special arbitration tribunals were established for the determination of matters arising out of the various orders made under the 1915 and 1916 Acts.

Under the procedure of the Munitions of War Acts, arbitration became the normal method for the settlement of labour disputes. From the point of view of the workpeople, it was more expedient to claim arbitration under the Acts than to endeavour to secure a settlement by conciliation machinery or other negotiations and, moreover, an award under the Acts was statutorily enforceable. On the employers' side also, arbitration was often found to be the most satisfactory procedure; when so much work was being done for Government purposes, the employers' financial interest in the result of negotiations was diminished. A further development was that in many industries (e.g. the railways and coal mines) the conciliation boards fell into abeyance. During the war wages claims were necessarily determined largely in reference to the cost of living and consequently unions made claims for national advances in place of district claims. The net result, therefore, was a very large increase in the number of arbitrations under Government auspices and a falling off in conciliation settlements. During the four years 1915-18, nearly 8,000 awards were issued by arbitration tribunals under the Munitions of War Acts and, to a small extent, under the Conciliation Act, 1896. The Munitions of War Acts also introduced certain other features which have a considerable bearing on the settlement of labour differences, such as the power given to the Minister of Munitions under the Munitions of War Act, 1917, to extend an award, applying to the greater part of an industry, to other firms not party to the award but engaged on the same class of work.

It may be recorded that the New Ministries and Secretaries Act, 1916, transferred the powers of the Board of Trade under the Conciliation Act and the Munitions of War Acts to the newly created Ministry of Labour.

Wages Regulation Act.—Immediately after the Armistice, the Government, at a national conference of employers and workpeople on Nov. 13 1918, intimated that their post-war policy in relation to labour disputes was to leave employers and workpeople to adjudge as far as possible their own differences. Certain proposals were placed before the conference for the period of transition while Industry was changing over from war to peace conditions. These proposals, which were accepted by the employers and by the trade unions, were embodied in the Wages (Temporary Regulation) Act. The broad principle of that Act was to maintain as minimum rates, for a period of six months, the standard district rates existing at the date of the Armistice. Wages having been regulated during the war mainly in relation to the cost of living, they had at the date of the Armistice reached a level far above the pre-war rate. It was not anticipated that the cost of living would fall considerably immediately after the Armistice, while there was a fear that rapid demobilization might result in a serious break in the labour market. This fear was to recur at attempts at wage reduction of a kind which would lead to great industrial unrest. The Act repealed the prohibition of strikes and lockouts contained in the Munitions of War Acts, and limited compulsory arbitration to the wage standards dealt with in the new Act; it continued, in the Interim Court of Arbitration, the principle of a central arbitration tribunal which had been so successful in the form of the Committee on Production.
The termination of the war was followed by an outburst of unrest, and the position became so serious that in Feb. 1919, the Government summoned a further national conference of employers and workpeople to consider the position. A committee appointed by the conference subsequently made a number of proposals on questions relating to hours, wages, and general conditions of employment, unemployment and its prevention, and the best methods of promoting cooperation between capital and labour. As regards wages, one of the recommendations was the continuance of the Wages (Temporary Regulation) Act, 1918 for a further period of six months, and this recommendation was adopted by the Government in the Wages (Temporary Regulation) Extension Act, 1919.

In consequence of this period of unrest, special reference may be made to the coal-mining industry where the position became so acute in connexion with demands of the Miners' Federation, including a demand for the nationalization of the industry, that in Feb. 1919 the Government set up a committee (under the Coal Industry Commission Act) to inquire into the position of, and conditions prevailing in, the industry. (For the reports of this commission see Cmd. 359, 360 and 361 of 1919.)

During the war a number of committees and commissions had been appointed by the Government to inquire into problems connected with labour disputes. Thus, there were (2) an inquiry by Lord Balfour of Burleigh and Sir Lynden Macassey, K.C., into "the cause and the circumstances of the apprehended differences affecting munition workers in the Clyde district," Dec. 1915; (2) commission appointed in June 1917 to "inquire into and report upon industrial unrest and to make recommendations to the Government"—reports summarized by Mr. G. N. Barnes, M.P. (Cd. 8666); (3) committee under the chairmanship of Mr. Justice Atkin, appointed in 1918 as a result of a strike of omnibus workers to investigate and report as to the relations which should be maintained between the wages of men and women, having regard to the interests of both, as well as the value of their work (Cd. 355); (4) committee appointed in 1918 under the chairmanship of Mr. Justice McCardle to inquire into matters connected with a strike of munition workers at Coventry and elsewhere in connexion with the Government embargoes on the transfer of employment of skilled men; and (5) committee appointed in Oct. 1916, under the chairmanship of Mr. J. H. Whitley, to make suggestions for securing a permanent improvement in the relations between employers and employed (Cd. 9153, etc.).

Whitley Committee.—The recommendations of the last-named committee were of far-reaching importance and in fact formed the basis of the Government's post-war policy in regard to industrial relations and strikes and lock-outs. The committee recommended the setting up of joint industrial councils (now sometimes called "Whitley Councils") in trades where employers and workpeople were sufficiently organized, the extension of trade boards for poorly organized trades, and the temporary establishment of other bodies for "intermediate" trades. The committee's recommendations with regard to the establishment of joint industrial councils were prefaced by a declaration to the effect that in the interests of the community it is vital that after the war cooperation of all classes, established during the war, should continue, more especially with regard to the relations between employers and employed, and that, for securing improvement in the latter, it is essential that any proposals put forward should offer to workpeople the means of attaining improved conditions of employment and a higher standard of comfort generally, and involve the enlistment of their active and continuous cooperation in the promotion of industry. The committee then recommended that H.M. Government should propose without delay to the various associations of employers and employed the establishment for each industry of an organization, representative of employers and workpeople, to have as its object the regular consideration of matters affecting the progress and well-being of the trade from the point of view of all those engaged in it so far as this is consistent with the general interest of the community. The committee recommended that the national councils should be supplemented by the creation of district councils and works committees and deal with district and local matters respectively and they defined the questions with which the national councils, district councils, or works committees might deal. The Government intimated their acceptance of the recommendations of the Whitley Committee and at this date (Dec. 1920) 63 joint industrial councils have been established in various industries in the country. The Government have applied the machinery in their own industrial establishments and also in the civil service. The committee also issued a report on conciliation and arbitration and their recommendations thereon were as follows:

(2) Whilst we are opposed to any system of compulsory arbitration, we believe there is a case for the expansion of voluntary machinery for the adjustment of disputes. Where the parties are unable to adjust their differences, we think that there should be means by which an inquiry into the facts of the case may be made and the circumstances of the dispute and an authoritative announcement made thereon, though we do not think that there should be any compulsory power of delaying strikes and lockouts.

(3) We further recommend that there should be established a standing arbitration council for cases where the parties wish to refer any dispute to arbitration, though it is desirable that single arbitrators should be available where the parties so desire.

The constitution and functions of the joint industrial councils are in many respects similar to those of conciliation boards, but whereas the last-named are formed by the Government to deal with questions affecting rates of wages and conditions of labour or demarcation of work between various classes of operatives, the industrial councils are designed to have a wider scope and can take into consideration matters of every kind which appertain to the welfare and smooth working of the industry. The encouragement of joint industrial councils formed a definite part of the broad policy of the Government to encourage industries so far as possible to settle their own disputes. In certain large and important industries (coal-mining, railways, agriculture) where the Government have not yet found it possible to relinquish their special war relations, while joint industrial councils have not been established, the Government has taken steps to secure that the questions arising in these industries may be referred to arbitration and conciliation. For example, in coal-mining special machinery is provided for by the Mining Industry Act of 1920; for railways, the Government have established special conciliation machinery, including a national wages board; and in agriculture, wages boards have been established under the Corn Production Act, 1917, and Agriculture Act, 1920. The voluntary conciliation machinery which was the fundamental factor in this country before the war, but which was in suspense during the war, is therefore now being re-established on a substantially wider basis and the result of the establishment of the industrial councils has undoubtedly been greatly to increase the opportunities for the conciliatory discussion and adjustment of labour disputes.

The recommendation of the Whitley Committee with regard to trade boards was also adopted by the Government and, following the passing of the Trade Boards Act of 1918, the Government embarked on a policy of the extension of trade boards. These boards differ from WhitleyCouncils in that they consist partly of representatives of the employers and workpeople in the trade and partly of persons appointed by the Government; their determinations are statutorily enforceable as minimum standards of working conditions and the members of the boards are appointed in industries where the organization of employers and workpeople is weak. While they would not normally be included in the definition of conciliation machinery, it is advisable to note them in connexion therewith as by establishing minimum rates of wages in low-paid industries, they tend to remove one of the root causes of labour unrest. Moreover, the meetings of employers and employed for trade board business afford opportunities for the mutual discussion of other matters and thus tend to improve the relations between the parties.

Industrial Courts Act.—The recommendations of the Whitley Committee on the subject of conciliation and arbitration formed the basis of the Industrial Courts Act, which was passed in Nov. 1919. This Act sets up alternative forms of tribunals to which recourse can be had, if both parties to a dispute agree. Of these,
the principal tribunal is a permanent court of arbitration (called 
the Industrial Court) consisting of persons appointed by 
the Minister of Labour, of whom some are independent persons, 
some are persons representing employers, and some are persons 
representing workmen. There is a permanent president of the court and in addition there are 
chairs of divisions of the court. The other forms of tribunal 
provided for by the Act are (a) single arbitrators and (b) boards of 
arbitration consisting of one or more persons nominated by 
the employers, an equal number nominated by the workpeople, 
with an independent chairman nominated by the minister. For 
the purpose of these boards of arbitration, panels of persons 
(including women) suitable to act in the respective capacities are 
constituted by the minister. The Industrial Courts Act further 
empowers the Minister of Labour in the case of disputes, either 
prejudiced or existing, to appoint a court of inquiry, one of the 
objects of which is to put before the public an impartial account 
of the merits of the dispute. The Act continued until Sept. 30, 
1920 the principle of the Wages (Temporary Regulation) Acts, 
1918 and 1919, that broadly speaking the wages ruling at the 
time of the Armistice should remain in force as standard minimum 
rates (The British Act, 1886, continues in existence, but in 
proposals provisions are covered by the Industrial Courts Act.) 
The provisions in relation to the appointment of courts of 
inquiry, for the purpose of making a public inquiry and public 
report upon the facts and circumstances of a dispute likely 
to affect seriously the public interest, is based upon the Canadian 
Industrial Disputes Investigation Act, but while the British Act 
like the Canadian Act) provides for the grant to the courts of 
inquiry of certain compulsory powers to secure the attendance of 
witnesses, the production of documents, etc., it differs from the 
Canadian Act inasmuch as it makes no attempt to prohibit a 
strike or lockout pending the inquiry. The British Act relieves 
entirely the public of the duty of deciding upon the agreement 
upon the facts and circumstances of the disputes concerned. 

During the first year of the Industrial Courts Act over 500 
cases were referred to the arbitration of the industrial court, a 
number of the cases being of considerable importance. A list 
concerning the principal issues in the disputes in the industry. During the same 
period courts of inquiry were appointed in three instances with 
satisfactory results. 

Compulsory Arbitration.—Certain aspects of conciliation and 
arbitration procedure in the United Kingdom have aroused 
special consideration during recent years. From time to time, 
proposals have been put forward in favour of declaring strikes and 
lockouts illegal and instituting compulsory arbitration; at trades 
union congresses, however, resolutions in favour of compulsory 
arbitration have been defeated by large majorities. But on this 
basis have existed for some time in Australia and, under the 
pressure of war conditions, legal prohibition of strikes and lock-
outs and compulsory arbitration were introduced in the United 
Kingdom. Success was, however, only partial, and the experience of this period affords no reliable guide as to what might be 
expected to occur under more normal conditions. A large number 
of strikes and lockouts, some of considerable magnitude, did in 
fact occur, and probably the principal influence in restricting the 
number of stoppages during the war period was the patriotic 
spirit and the determination on the part of all classes to bring 
the war to a successful conclusion. The Whitley Committee on the 
relations between employers and employed came to the following 
conclusion on this subject:

We are opposed to any system of compulsory arbitration; there 
is no reason to suppose that such a system is generally desired by 
employers and employed and, in the absence of such general accept-
ance, it is obvious that its imposition would lead to unrest. The 
experience of compulsory arbitration during the war years has 
shown that it is not a successful method of avoiding disputes, and in nor-
mal times it would undoubtedly prove even less successful. Dis-

The increased organization of employers and workpeople in the 
United Kingdom which resulted from war conditions has had sub-
stantial effects on the machinery for conciliation for employees. Such an 
organization of some sort was for a while seen as a method of combination, but attempts at general strikes after the war have also 
indicated the limitations of the strike weapon, and in addition 
have imposed on the trade union movement the need for coordina-
tion. This has having effect in the proposals now under discussion for the 
establishment of a General Staff for Labour. On the other 
hand, recent strikes have produced in certain quarters demands for 
Labour realized from some means of action—such as a ballot—to be taken in 
a manner prescribed by statute.—prior to a declaration of a strike, 
but the trade unions are not likely willingly to forego the 1 lighting
strike." With organization comes the establishment of machinery for the mutual protection of different classes of workpeople and discussion of disputes to an amicable settlement: on the other hand, with employers and workpeople strongly organized in their respective associations, the claims advanced on behalf of labour develop beyond claims about wages or hours of work, to include questions such as labour's right to share in the management and control of industry. Further, when a strike or lockout does occur, it often has far-reaching effects extending beyond the merely industrial questions, such as strikes or lockouts. It is largely on the ground of the effect on the public that the State has become more and more involved in the legislation on strikes and lockouts, particularly in the group of industries known as "public utility" services, and, failing settlement, of taking exceptional powers such as those conferred on the Government in time of war. Generally speaking, the development of organization has been that the larger trade unions appear in some instances to have become over-centralized, and in this connexion the growth of works committees may well be worth watching. Generally, also, there has been in the United Kingdom a very marked increase in the regular meetings of employers and employed for the purpose of discussion of matters which may be at issue between them; and while it cannot yet be said that there is freedom from suspicion and distrust there is clear evidence of the growth of a desire for full and frank discussion of all matters affecting the relations between employers and employed. Discussion and conciliation machinery of the kind in operation is largely based on the acceptance of organization by employers and workmen into their respective associations; the joint industrial councils scheme is based on organization, and the Industrial Conciliation and Arbitration Act provides a different machinery, be it referred by the Ministry of Labour to arbitration until there has been failure to achieve the settlement by the conciliation machinery existing in the industry.

British Colonial Legislation

In connexion with British colonial legislation on the subject of conciliation and arbitration, it may be recorded that in Canada the Dominion Conciliation and Arbitration Act continues to represent the legislative position of the Government. In Australia a considerable number of amendments have been made. In New Zealand the Industrial Conciliation and Arbitration Act of 1907, as amended, is intended to enable strikes and lockouts to be amended to meet alterations in conditions of employment and the cost of living. Further, the existing machinery was strengthened by the Labour Disputes Investigation Act, 1913, which provides machinery for the investigation of disputes not coming within the scope of the Industrial Conciliation and Arbitration Act. The 1913 Act provides for conference of the parties with a view to securing an amicable settlement, or, in the alternative, investigation by labour dispute committees. Before a strike may lawfully take place, a ballot of the workers is taken by the registrar of industrial unions and the result of the ballot publicly notified. After the lapse of the period allowed for ballot publication, if no alteration has been made to strike, whatever the result of the ballot may have been. Similar provisions are made to apply in the case of lockouts. Most of the states of Australia have passed new legislation on this subject. In Victoria, the Conciliation and Arbitration Act of 1906 and 1916, and in Tasmania under the Wages Boards Acts of 1910, 1911, 1913 and 1917, there is a wages board system; in Victoria there is no prohibition of strikes and lockouts, but in Tasmania penalties are provided for stoppages of work account on any matter in respect of which a board has made a determination. In Western Australia, the Industrial Arbitration Act of 1912 provides for an Industrial Arbitration Court and prohibits strikes and lockouts, while in New South Wales under the Industrial Arbitration Acts of 1912, 1916, 1918 and 1919, in Queensland under the Industrial Arbitration Act of 1916, and in South Australia under the Factory Acts of 1907, 1915 and 1916, the practice of the Labour Disputes Investigation Committee and the Conciliation and Industrial Arbitration Act of 1915 and 1916, there are both a wages board and an industrial court system. In accordance with the provisions of the Acts in New South Wales and Queensland, the industrial tribunals have been exercising the functions of wages boards, and the work of the existing boards has been greatly curtailed. Under the industrial court system, an industry does not technically come under review until it has been definitely organized through the creation of a joint industrial council, or, in the case of a new industry, the president of the court power to summon a compulsory conference. The Commonwealth of Australia has also recently amended its procedure by means of the Industrial Peace Act, 1920, which sets up in each industry a council formed into Federal and District branches, considering matters affecting the prevention and settlement of trade disputes and further authorizes the governor-general to set up special tribunals (Commonwealth and District) empowered to investigate and report on pay disputes and to determine the parties to the dispute, or (2) as to which the tribunal or other appropriate authority has convened a compulsory conference and a complete agreement has not been reached.

The movement in the United States is dealt with in a subsequent section of this article. A considerable number of other countries have amended their laws on the subject of the settlement of strikes and lockouts. In Norway a law dated Aug. 1912 introduced for the first time in that country machinery for the settlement of labour disputes by the State. One noteworthy feature of the new measure was the application of the principle of compulsory investigation and delay before a stoppage of work, a measure which respect it resembles the Colonial Industrial Disputes Investigation Act of 1907. Another noteworthy feature is the compulsory registration of trade unions and employers' associations and the recognition and regulation of agreements in respect of matters dealt with by the courts for the prevention and settlement of labour disputes. Questions arising out of existing collective agreements must be brought before a specially constituted labour court, while those originating from new disputes after alteration of the wages boards to be set up throughout the country. This was followed in 1916 by a compulsory arbitration law. It should also be noted that the Provisional Works Councils Act of July 1920 requires the establishment of a council for each country, and a competent employment is regularly maintained throughout the year not less than 50 workers on a demand of one-fourth of the workpeople. The functions of the councils are advisory only; they can give no opinion on matters concerning the establishment or so far as they relate to working conditions, rates of remuneration, workshop regulations, welfare institutions, etc. No penalty is laid down for failure to comply with the terms of law.

In Sweden the law of 1906 providing for the appointment of conciliators was subjected to inquiry from 1916 onwards with a view to revision and, as a result, it was superseded by three new measures all of which are in operation. The law of 1919 amended the original law in respect of the appointment of local official conciliators; the second establishes a permanent Arbitration Court consisting of three impartial persons nominated by the representatives of employers and workpeople to deal with disputes arising out of collective agreements, without recourse to strikes or lockouts or to legal process in the ordinary courts; while the third empowers the Government, on the recommendation of the Arbitration Court, to appoint arbitrators for individual disputes arising out of collective agreements and involving matters of minor importance. Recourse to the Arbitration Court is voluntary, and the bill was passed for settling industrial disputes. Strikes and lockouts without recourse to conciliation are prohibited in establishments employing ten or more persons. When a dispute arises, a conference is required to be held in the presence of the minister of the works of the town and if the dispute is not settled, it may be referred to the Arbitration Court. The decision arrived at is obligatory on all parties.

In Switzerland the Factory Act of 1877, which was amended in certain respects in 1905, was repealed and superseded by a new Factory Act of June 1914. In accordance with the new law, a council is set up for averting strikes and lockouts. The Act provided, with a view to the amicable settlement of disputes which are calculated to lead to a strike or lockout, for the appointment of permanent cantonal conciliation committees which might intervene either on their own initiative or at the request of the authorities or of the parties directly concerned. Persons summoned before these tribunals are obliged, under penalty, to appear. A certain number of employers and workpeople in any industry may mutually agree to constitute a conciliation committee so far as those employers and workpeople are concerned.

Apart from the new Government of Dec. 1918 continued, for the purpose of the settlement of labour disputes and pending arrangements of further statutory regulations, the system of district conciliation councils was established during the war. The constitution, functions and powers of these conciliation committees are similar to those of the industrial courts which have been in existence in Germany for many years, in so far as they have been fitted to the present conditions and the war. An Act of Jan. 1920 requires the setting up of works councils, one of whose functions it is to appeal to the conciliation committee or to an arbitration board to be agreed upon, failing a settlement in that manner. It may be noted that the industrial district councils are vested with very wide powers such as the right to demand information of all business transactions. The works councils are to be united in district councils whose work will be co-ordinated with that of employers in district economic councils and in a federal economic council. A provisional federal economic council has already been established although the subordinate organizations are not yet in existence. A
bill has been under consideration during 1920 in which it is proposed to make recourse to conciliation compulsory and to make the decisions of the conciliation boards obligatory (a) in public services where they are established by law, and (b) in industries where there exist by reason of a collective agreement; in other cases if a strike or lockout may be called in spite of a decision, if a ballot is taken and a two-thirds majority is secured in favour of a stoppage. Meanwhile, as the outcome of a strike of electrical workers in Berlin illustrates, the investigations and conciliation orders issued are not always effective, and lockouts in establishments supplying the community with gas, water, or electricity. Under the order, lockouts and strikes in such establishments are permissible only after the lapse of three weeks from the publication of an award by the competent conciliation committee; persons who incite to a strike or lockout, prohibited under the order, or who, for the purpose of bringing about such a strike or lockout, commit certain acts of intimidation or compel the establishment by which the regular carrying on of the undertaking is hampered or rendered impossible, are liable to imprisonment or a fine—liability to penalty is also incurred by anyone who proclaims a lockout in the circumstances defined; if the order so granted indicates that they cannot be brought entirely or partially to a standstill as a result of a lockout or strike, the Minister of the Interior is empowered to take emergency measures for the maintenance of supplies, including the satisfaction of the workers. The cost of putting such measures into operation falls upon the owner of the establishment.

The sources of the information are the series of reports and periodicals issued formerly by the Board of Trade and now by the Ministry of Labour, viz.: Proceedings under the Conciliation Act, including latterly work done under the Ministry of Labour; reports of the Industrial Courts; Strikes and Lockouts; these reports contain a particular of the work of voluntary conciliation and arbitration boards; second Report on Rules of Voluntary Conciliation and Arbitration Committees; third, Labour Statistics; the monthly Labour Gazette contains data as to the position in the United Kingdom and abroad; and the information as to the dominions and foreign countries is now supplemented by a new quarterly periodical entitled Labour Overseas. Special publications of value are the series of reports of the Committee on the Relations between Employers and Employees in New Zealand (as well as the Whitley Committee’s Report) (Cmnd. 9153, etc.); Memoranda issued by the Board of Trade on Laws in the British Dominions and Foreign Countries affecting strikes and lockouts with special reference to Public Utility Services (Cd. 6081 of 1912); Report of Sir George Alexander Bright on the Industrial Disputes Investigation Act of Canada in Dec. 1912 (Cd. 6603 of 1912); Report of the Industrial Council of 1913 on Enquiry into Industrial Agreements (Cd. 6053); and Reports of the Coal Industry Commission (Cmnd. 539, 360, and 156 of 1910); see also the reports on the various countries, e.g. New Zealand Official Year Book; Official Year Book of the Commonwealth of Australia; Reports of the United States Department of Labour; etc. See also 17th Annual Report of the Conciliation, Labour Regulation, Strike, and Lockouts, Trade Boards.

United States

In the United States the movement for state legislation for voluntary arbitration and conciliation progressed steadily, until in 1920 a majority of states had legislation providing for the settlement of industrial disputes. Many of these states have permanent boards of conciliation and arbitration with two to six members, though three is the usual number. In some states the labour commissioner acts as mediator, while in others a chief mediator is appointed by industrial commissions together with temporary boards of arbitration. Twenty states provide for compulsory investigations, and in several others it is permitted by local laws. In 17 states the voluntary agreement to arbitrate must contain a provision to abstain from strikes and lockouts during arbitration proceedings, and in two states, Colorado and Kansas, make strikes and lockouts unlawful and a ground for fines and imprisonment. The law of 1915 gives to the Industrial Commission of Colorado the power to compel a hearing in the case of an industrial dispute and to deliver an award which is not mandatory. As in the Canadian Industrial Disputes Act, change of terms of employment, strikes and lockouts are prohibited, if the parties invest in a President, who after a hearing and award, if such hearing is started within the time of notice. Though it does not prohibit the right to strike, it delays the strike. Kansas, an agricultural state, by creating, in 1920, a Court of Industrial Relations, established compulsory arbitration.

The law applies to industries connected with the manufacture of food products, clothing and wearing apparel in common use; to mining or the production of fuel; to transportation of the above-mentioned articles; and to all public utilities and common carriers, which are declared to be affected with a public interest and subject to supervision by the state. The court, which consists of three judges appointed by the governor for a three-year term, is authorized to summon the parties to a dispute before it, to investigate the conditions of the industry and to make a reasonable award. It may bring suit in the Supreme Court of the state to compel compliance with any of its orders. Either party, if aggrieved by an award, may sue in the state courts in regard to the Industrial Relations to issue a reasonable order. Though the law recognizes the right of collective bargaining and the right of the individual to quit work, the right of labour to enforce its claims is forbidden. In the case of actual suspension or limitation of the operation of an industry, the court may take it over and operate it during the emergency.

Federal Legislation.—The Federal legislation on arbitration and conciliation 1888 and 1895 applying to common carriers has been superseded by three Acts: the Act of 1913 (the Newfoundland Act); section 8 of the Act creating the Department of Labour (1913); and title III. of the Transportation Act of 1920. The Newfoundland Act provided for the appointment of a Federal board for voluntary mediation and conciliation to consist of three members, a Commissioner and two other Government officials, appointed by the President with the advice and consent of the Senate. In four years this board functioned in 71 controversies, 14 of which were settled partly or wholly by arbitration and 52 by mediation. Failure of the Act, however, to meet the railway labour crisis in the fall of 1916 and again in March 1917 resulted in the first instance in Congressional action in the shape of the Adamson law granting the basic eight-hour day to trainmen, and in the second instance in the appointment of a Federal board for the settlement of the Railway disputes. This meant, in effect, the breakdown of the Newfoundland Act, though it continued on the statute books subject to the limitation imposed on it by the Transportation Act of 1920. When the Government assumed control of the railways in Dec. 1917, a labour policy was immediately agreed upon. A Railway Wage Board was appointed to make recommendations to the Director-General, and a Division of Labor, headed by a brotherhood (union) official, was created to be the connecting link between employees and officials on the one hand and the Railway Boards of Adjustment. Later a permanent Advisory Board on "Railway Wages and Working Conditions" was created. The orders of the Director-General formulated a liberal labour policy, and machinery for handling disputes under these orders was established in the form of three Boards of Adjustment, composed equally of representatives of the administration and the workers.

A similar policy was adopted in the Transportation Act of 1920, which makes it the duty of the railways and their employees to "exert every reasonable effort and adopt every available means to avoid any interruption to the operation of any carrier," growing out of any dispute involving grievances, rules or working conditions. In cases a dispute is to be referred to the President, or to a conference, of representatives of each side. Disputes that cannot be settled in this way are to go before Railway Boards of Labor Adjustment which may be established by agreement between any road or group of roads and the workers. Except for a stipulation that these boards must contain representatives of organized labour, their size and composition are left to the discretion of the parties concerned. Matters may come before the Adjustment Boards either upon application by the road or the organized workers affected, or upon written petition of a hundred organized workers, or upon the road's own motion or upon the request of the Railroad Labor Board. This last-mentioned board is set up by the Act as the final tribunal for the settlement of railway labour disputes. It is composed of nine members appointed by the President with the advice and consent of the Senate to represent in equal proportion the workers, the employers and the public. During their five-year term of office, members of
the board must not be active members or officers of labour organizations or hold stocks or bonds of any carrier. Disputes may come before the Railroad Labor Board either upon failure of Adjustment Boards or directly. A majority vote is all that is necessary to constitute a decision except on matters taken up directly, in which case one of the members representing the public must concur in the decision. It has power to suspend any decision on wages made by the initial conference if, in its opinion, such a decision involves increases in wages or salaries which would necessitate a substantial readjustment of rates. In such cases the board must, after hearings, affirm or modify the suspended decision, and must also hold hearings on alleged violations of decisions and publish its decisions.

The Act of March 4, 1913, creating a Department of Labor, provides that the Secretary of Labor shall have power to act as mediator and to appoint conciliation boards to settle industrial disputes, whenever in his judgment the interests of industrial peace require it to be done. In case mediation fails, arbitration may be proposed by the mediators, who cannot act as arbitrators. During the five years inclusive, 1913-19, the Secretary of Labor took cognizance of 3,614 cases and effected 2,529 adjustments. During 1916 alone, 1,780 assignments of commissioners of conciliation resulted in 1,223 adjustments. In addition to the direct efforts of the Secretary of Labor, two other Boards of Labor Adjustment were established as part of the war machinery of the country. The President’s mediation commission was appointed in the fall of 1917 to conduct an investigation into the underlying causes of labour unrest which was threatening the output of material needed for war industries and to make specific adjustments. The Secretary of Labor was appointed as Chairman of the Commission. It made investigations in the copper mines of Arizona, the California oil-fields, the Pacific Coast telephone dispute, the unrest in the lumber industry of the north-west, and the packing industry. Settlements were made in all disputes except in the lumber industry, generally after arbitration had failed. In Jan. 1918, the Secretary of Labor, upon conciliation to manage disputes, and employer appointed a War Labor Conference Board to devise a method of labour adjustment which would be acceptable to employers and workers.

As a result of the Conference Board’s report, the National Labor War Board was created by presidential proclamation in April 1918. The membership consisted of two joint chairmen, five representatives of employers’ organizations and five representatives of employers’ organizations. As stated in the Proclamation, its powers and duties were to settle by mediation and conciliation controversies arising between employers and workers in fields of production necessary for the effective conduct of war, or in other fields of national activity, delays and obstructions in which might, in the opinion of the National Board, affect detrimentally such production and to provide necessary machinery for these purposes. Its authority did not extend to controversies between employers and workers in any field of industrial or other activity where there was by agreement or by Federal law a means of settlement which had not been invoked. This provision excluded from the jurisdiction of the Board, except by way of appeal, a large group of cases. The shipbuilding industry had set up by agreement its own Labor Adjustment Board; the Ordnance Department and other producing departments of the Government had created special industrial service sections to consider the complaints of their employees; the coal mining industry had its labour policy controlled by agreements of all parties with the Fuel Administration and the Government had adopted a separate labour policy for the railways. The statement of principles and policies contained in the report, which governed the decisions and which became an official expression of the Government’s labour policy, was as follows: (1) abolition of strikes and lockouts during the war; (2) equal right of employers and workers to organize without discrimination; (3) right of collective bargaining; (4) observance of the status quo and of open shop or preference agreements given establishment and as to union standards of wages, hours and other conditions of employment, except that the War Labor Board might grant improvements in labour conditions as the situation warranted; (5) maintenance of established safeguards and regulations for the protection of the health and safety of the workers; (6) payment of equal wages for equal work; to women in industry and allotment of tasks proportionate to their strength; (7) recognition of the basic eight-hour day in all cases in which existing laws required it, in other cases settlement of the question of hours with regard to Governmental necessities and the welfare, health and proper comfort of the workers; (8) maintenance of maximum production; (9) regard to be had for labour standards, wage scale and other conditions prevailing in the localities affected, in fixing wages, hours and conditions of labour; (10) right of all workers to a living wage which insures subsistence of the worker and his family in health and reasonable comfort. Provision was made for the establishment of a National Board, under the control of the Industrial Board and in event of failure of local machinery, for hearings before the National Board. When the National Board found it impossible to settle the controversy, provision was made for the appointment of an umpire by the National Board or by the President from a panel of disinterested persons. In the enforcements of its awards, the National War Labor Board had no special legal sanction or penalty either to force any party to submit disputes to arbitration or to enforce its awards. So outspoken however was public opinion on the necessity of avoiding interruptions in the war industries and so far-reaching were the wartime powers of the Federal government, that the enforcement by the Board of the industrial peace provided by the War Labor Board was sufficient to make the industrial peace which the Board of the awards. In only three cases were the Board’s awards resisted. In two instances where the employers discriminated against the union employees and refused to abide by the decision in favour of the men, the President was sustained by Congress in taking over the industries. In the case of the strike by the organized workers at Bridgeport, Conn., against the Board’s award, the President’s threat of unemployment enforced by Governmental agencies compelled the men to return to work.

Besides legislative programmes, the Federal Government has made several other attempts to devise plans for the adjustment of labour disputes. In 1913 President Wilson appointed the Industrial Relations Commission to diagnose the cause of industrial unrest, and in the fall and winter of 1910 he appointed two industrial conferences to formulate a reconstruction labour policy. None of the programmes suggested has been given practical application. Experience during the war demonstrated the possibility of successful Government intervention in industrial disputes through mediation. Even voluntary arbitration was resorted to only in a few instances. Legislation was still needed in 1921 to extend the field of Federal mediation with an apparatus of interest, which will be described below, and disputes so vital and comprehensive in extent that existing state agencies are unable to meet the situation. Though the Secretary of Labor is empowered to intervene in such cases, his intervention introduces political and trade union partisanship, which is objectionable to the parties to the dispute. The rapid increase of state agencies has created the need for cooperation between the state and Federal agencies. (For collective bargaining and arbitration in private industries see Trade Unionism.)

ARBUTHNOT, SIR ROBERT KEITH, 4TH BART. (1854-1916), British sailor, was born March 23, 1854, and succeeded his father, the 3rd bart., in 1889. He entered the navy in 1877 and was promoted commander 1879, captain 1902 and rear admiral in the 2nd Battle Squadron 1913. Early in 1914, in command of the British fleet over the 1st Cruiser Squadron and led it in the battle of Jutland, flying his flag in the "Defence," which was sunk with the loss of all on board May 31, 1916.
ARCH, JOSEPH—ARCHAEOLOGY

ARCH, JOSEPH (1826-1910), British labour leader (see 2,432), died at Barford, Warwick, Feb. 12 1919.

ARCHAEOLOGY: EGYPT AND WESTERN ASIA.—During 1910-20 advances in Egyptian archaeological knowledge have been slow. Of course, generally speaking, less advance was made than in many previous decades, owing to the interregnum caused by the World War, when all British, French, German, and Austrian work was held up, and only the Americans and to a lesser degree the so-called "Egyptian" Service of Antiquities (manned by French and English) did any digging at all; while in all the European countries the energies of all the archaeologists who were not supernannuated were transferred to the field of war, and there was no time left to write little papers, still less big books. And several, especially in France and Germany, made the great sacrifice which see below, but some who in return to get old Nilotic inhabitants, who were probably related to the true Semites of Arabia; but the hieroglyphic system seems to have developed in the Delta, and is very probably to be ascribed to the "Armenoids." The Osiris cycle of legends seems to belong to these people. Osiris and Isis are closely connected with Syria and the Lebanon in legend; the Ded or sacred pillar of Osiris is doubtless really a representation of a great cedar with its horizontally outspreading branches; another of the sacred Egyptian trees is obviously a cypress; corn and wine are traditionally associated with Osiris, and it is probable that corn and wine were first domesticated in Syria, and came thence with the gods Osiris and Re (the sun god of Heliopolis) into the Delta. Syria in fact is beginning to take shape in our minds as perhaps the most ancient seat of civilization in the world, the common source from which Babylonia and Egypt derived those items of culture in which, in the early period, they resemble one another. It remains for excavation to show whether this hypothesis is or is not correct. And the question whether the "Armenoid" conquerors of Egypt and founders of the kingdoms there, who came from Syria, were Semites still remains unanswered. If they were Semitic speakers, the present facial contours of the northern Semites, which have spread all over the world, are Semitic at all: for the Egyptian Armenoids in the statues of the Old Kingdom look like Europeans, and must have been of "European" blood.

These new probabilities open up considerable possibilities in research with regard to the relations of the early Minoans and other Aegeans with Syria and Egypt and the undoubted fact of the resemblances of Minoan on the one hand to Syrian and Egyptian religions and funerary practices, and on the other hand to those of the Etruscans. The facial contours of the modern Jew are predominantly those of the ancient Hittite, who was certainly not a Semite. One has hitherto supposed that he was related to the Mediterraneans, the race to which the Bronze Age Greeks and Italians belonged; but this supposed connexion may well break down in the matter of skull form, as the Hittite skull, like that of the modern Anatolian, probably inclined to be brachycephalic, whereas that of the Mediterranean inclined in the other direction. And now the Bohemian Assyriologist Prof. Hrozny has brought forward evidence that the cuneiform script, adopted by the Hittites from the Mesopotamians expressed an Indo-European language. This conclusion is not yet universally accepted, but it seems difficult on the evidence to avoid the conclusion that Prof. Hrozny is right, and if so the curious resemblances of some of the externals of Roman and Hittite religion, and the legendary and other connexions between the Etruscans and Asia Minor, are seen in a new light.

If the Hittites were Aryans, one can hardly suppose a primeval Aryan element in Anatolia. The Indo-Europeans whom we find in Mesopotamia (the Kassites and Mitannians) and in Palestine about 2400 B.C. can hardly have entered western Asia before 2000 B.C. or thereabouts, and it is probable that the Hittites belonged to the same wandering. On entering

ARCHAEOLOGICAL SURVEY OF NUBIA.—Michael Ventris and his colleagues have been occupied with the examination of mummy portraits at Thebes, and have published three portraits of the second Intermediate Period, illustrating a new style of painting. The results published in the "Archaeological Survey of Nubia" by Messrs. Reinsch & Firth have shown that the early culture of Nubia was closely akin to that of the predynastic Egyptians, who came at a period long anterior to its general introduction and replacing of bronze for weapons and tools. The Old Kingdom finds of iron are now seen to be nothing very extraordinary. But equally it is now impossible to cast any doubt upon them. The oldest iron weapon known was hitherto supposed to be an Egyptian halberd-head of the time of Rameses III., but Mr. Randall MacIver has recently discovered in a tomb of the XII. dynasty at the Second Cataract an iron spearhead which is eight centuries older; dating from about 2000 B.C. Iron was in fact both worked and used sporadically long before the Iron Age.

Interestingly conclusions as to the early chronology of Egypt have been derived from the systematic examination of the necropolises of Nubia, necessitated by the heightening of the Aswan dam, as a consequence of which the northern portion of the valley S. of the dam became flooded, so that a complete examination of the archaeology of the district had to be carried out in order to save historical evidence from destruction. The results published in the "Archaeological Survey of Nubia" by Messrs. Reinsch & Firth have shown that the early culture of Nubia was closely akin to that of the predynastic Egyptians, who came at a period long anterior to its general introduction and replacing of bronze for weapons and tools. The Old Kingdom finds of iron are now seen to be nothing very extraordinary. But equally it is now impossible to cast any doubt upon them. The oldest iron weapon known was hitherto supposed to be an Egyptian halberd-head of the time of Rameses III., but Mr. Randall MacIver has recently discovered in a tomb of the XII. dynasty at the Second Cataract an iron spearhead which is eight centuries older; dating from about 2000 B.C. Iron was in fact both worked and used sporadically long before the Iron Age.

Evidence is accumulating, though no completely satisfactory theory can yet be put forward, as to the northern origin of the dynastic Egyptians. Elliot Smith has shown the existence of the two racial stocks in Egypt, the predynastic Nilotic and the invading "Armenoid" from Asia, the man of higher cranial capacity to whom the blossoming of the Egyptian civilization and art out of primitive African barbarism is to be ascribed. This "Armenoid" stock must have come from Asia and, no doubt, reached Egypt by the Isthmus of Suez, but whence it came originally we do not know: Whether it was really Semitic we also do not know: whatever its skull may be its facial type is certainly not Semitic, whether of the fine pure Arab or the coarse big-nosed "Hethitized" types. It is sometimes almost central European in look.

How to equate this foreign civilizing race from Asia with the Semitic elements in the ancient Egyptian speech we do not yet know. But may be that the Semites and the "Hethites" may be that the Semites and the "Hethites"...
Anatolia they probably found the land at least as far W., as the Halys already occupied by Semites. This Semitic population in Anatolia is an important recent discovery. At the time of the great dynasty of Ur (c. 2500 B.C.) in Babylonia, the whole Arguan region was occupied by these Semites, who seem to have been most kin to the Assyrians. They were no doubt expelled or absorbed by the Hittites, but we have the proof of their existence and of the fallacy of the statement that the Semite never crossed the Taurus, in the cuneiform tablets written in their language which have been found near Karsibeyah and are now being published by various scholars. No doubt the Hittites learnt the use of cuneiform from these people. Whether the national hieroglyphic system of the Hittites expressed the same Indo-European language as, according to Hrozny, their cuneiform script does not know, but it is made by Campbell Thompson 11 and Cowley,12 while in themselves very interesting experiments, do not seem to take us further than previous attempts by Sayce and others. The supposition that the hieroglyphic system belongs to a late age, because it is chiefly found in the 10th and 9th century monuments of Carchemish, is improbable, as it bears all the characteristic marks of Hittitic nationalism, and is evidently a native invention. No people would have abandoned cuneiform for such a clumsy method of writing.

The excavation of Carchemish, lately suspended owing to political uncertainty in Syria, has been very interesting. The palace with its great relief-lined court and its water-gate of Hittite construction, the later Assyrian fortress, and the Hittite tombs with their characteristic pottery, are important results, and the whole work has been one of the major excavations of the last ten years, and has been fitly carried out by the British Museum, under the direction of Dr. Hogarth and Mr. Woolley.13 The excavations of Dr. Garstang for the university of Liverpool at Sakcoboz14, further N., not far from Sinjirli, the seat of earlier German work, have also produced interesting results. The peculiar characteristics of the Syro-Hittite art, and its relation to that of the Assyro-Babylonian, the art of the ancient Arameans, and of the civilization and art of the Near East. Equally interesting are the relation of the Syro-Hittite with the Minoan, and we seem to find in certain objects found in Egypt and Cyprus and dating probably from the 14th to the 10th centuries, proof of the existence of a mixed art of Syrian origin, probably in Sicilia (Alisha) at that time.15 Baron Oppenheim's excavations at Tell Halaf have resulted in the recovery of relics of barbaric style, simulating the Syro-Hittite, from the palace of a local king, Kapara, of about the same period as Sinjirli and Sakcoboz (9th-10th centuries B.C.), and pottery of all ages, going back to the chalcolithic period.16

The neolithic and chalcolithic pottery of Mesopotamia and Persia is one of the chief archaeological discoveries of late years in the Near East, and attention has recently been directed to it again by the important finds at Abu Shahrain (the ancient Eridu) and Tell el-'Obeid, near Ur. The excavations carried out for the British Museum at Shahrain by R. C. Thompson in 191817 and by Hall in 1919, and at Tell el-'Obeid by Hall in the latter year,18 have shown us that the painted ware of Susa and Musyana, discovered by de Morgan was not confined to Persia, but was the ordinary pottery of Babylonia in the prehistoric (chalcolithic) period. It seems characteristic of the neighbourhood of the gulf; the French excavations at Bandar Bashi on the Persian coast have revealed exactly similar ware. And small finds of it on other sites have shown that it was usual all over Mesopotamia, and connects on the one side with the early pot fabrics of Asia Minor and on the other with the pottery of Anau and the kurgans of Turkistan, found by Pumpey.19 Its place of origin is not yet known. Rostortz in his article drawing attention to the undoubtedly Semerian or sumerizing "Treasure of Astrabad"20 in N. Persia (which, it must not be forgotten, may have been an importation from Babylonia and not local art at all), seems to think a northern origin as probable as any other. But as a matter of fact an exclusively Elamite origin is not improbable, from the fact that its earliest and first types are found at Susa. Whether we should deduce from its common occurrence in Babylonia the existence of an Elamite population there in early times, later displaced by the Semarians, we do not know. Sumerian pottery is different, but there are traces of a transition period. One thing, however, is pretty certain, and that is that the numerous dates B.C. assigned to it by de Morgan and Pumpey cannot be accepted.

An argument for discontinuity of race is found in the fact that whereas the Semarians are never represented as using the bow, their predecessors certainly made flint arrowheads. The stone knives, arrowheads, clubs, hoe-blades, hammers, nails, awls, etc., associated with this pottery are of kinds which though simple and often crude in type are nevertheless not early, but date from the transition period to the age of metal and the earliest centuries of the Chalcolithic and Neolithic. Flint knives, stone knives, etc., but with none of the marvellous skill and artistry of the predynastic Egyptian flint-knapper; the early Babylonian used comparatively simple flakes and the wonderful sertation of the Egyptian knives was unknown to him though he made the saw-blades. Obsidian and rock crystal were also used for knife making. Celts, of the usual late neolithic type, were generally of green Jasper; hoe-blades (looking almost exactly like palaeolithic haches à main) of chert or coarse limestone; hammers of granite; mace-heads, of identical type with the early Egyptian, of diorite and limestone; nails of obsidian or smoky quartz, often beautifully made. All these stones were of course imported, as the Babylonian had no stone (except a rough coral rag) at hand as the Egyptian had. And many must have come from far afield. In later days, in the time of the Sargonids kings of Akkad or the monarchs of Ur, stones such as granite, basalt, diorite and dolerite were probably brought from the Sinaitic peninsula, if not from the western desert of Egypt, if the Red Sea coast is to be identified, as seems very probable, with Magan, "the place to which ships went," the land whence the Babylonians got some of their first stones for sculpture and architecture. Magan originally was probably a land on the S. coast of the Persian Gulf, but as the early navigators pushed their voyages further, the ships rounded the coast of Arabia, and came into the Red Sea, and the names of Magan and the neighbouring Meluhkka gradually extended westward, with the result that in late times to the Assyrians Meluhkka meant Ethiopia. Magan, however, probably never meant Egypt proper, the Nile land itself, or Egypt, would have been called Magan by the Assyrians in later times; it was called Mursi then and probably in early times also. So that we are not disposed to accept a recently propounded theory22 that a certain King Maniam of Magan who was overthrown by the Akkadid king Naram-Sin about 2350 B.C. was none other than Nenerma, the earliest king of Egypt, who is generally identified with Naram-Sin. Magan is a common Semitic name. We need not even suppose that this Maniam was a chief of the Egyptian Red Sea coast or even of Sinai. The Magan of which he was king need have been no further afield than the Oman peninsula. And the whole equation seems to break down on the matter of date, as it is quite impossible to bring Naramzer down to 2350 B.C. Naram-Sin was in reality a contemporary of the kings of the V. dynasty.

The question how far connexion was kept up between early Egypt and Babylonia by way of the Red Sea or across the desert is a very interesting one. An important point of recent importance is that this point has recently come to light in the shape of the carved hippopotamus-tusk handle of an Egyptian predynastic stone knife, said to have been found in the Wadi el 'Araq, on the right bank of the Nile opposite Nag Hamadi, and now in the Louvre.23 Og this remarkable object, which is certainly of predynastic Egyptian date (before 3500 B.C.), we see representations of early Egyptians and perhaps other tribes fighting, with ships, some like those represented on the Egyptian predynastic pots and others different, with high prows and sterna, and we also see a strange deity of Babylonian aspect. He is not identical with any known Babylonian deity, but he is the god of a people belonging to the Babylonian culture circle, probably of the inhabitants of the Red Sea littoral. The object is of Egyptian
workmanship, representing this powerful deity of the foreign sea people with whom the predynastic Nilotes no doubt often fought. This, by the way, points to the conclusion that Babylonian (Sumerian) culture and art were considerably older than the Egyptian; but we have no definite evidence yet on this point.24 Later points of artistic connexion may be seen when we compare the well-known bronze statues of Pepi I. and his son found at Hierakonpolis by Quibell with the copper lions discovered at Tell el-'Obeid near Ur by Hall two years ago.25 Dr. Reisner is of opinion that copper was first used in Egypt, and bronze certainly seems to have been used there first. The lions of 'Obeid date from about the Ur-Ninur period of Babylonian history, i.e. about 3000 B.C. or a century or two earlier; the Pepi statues are two or three centuries later. We see however the similarity of the metal-working of both countries at approximately the same time; both are in the same style of artistic development, the Egyptian perhaps the more advanced of the two, and (if the published analysis by Mosso is to be relied upon) with the additional technique of the alloy with tin, making the metal bronze, and so easier for the heads to be cast. The Sumerians cast the heads of their lions in copper, not always with successful results, and filled them with bitumen and clay (like the image in "Bel and the Dragon," which was "clay within and brass without ") to give them solidity. The bodies (or so much of them as ever existed, as only the fore parts remained) were hammered and wrought, like the bodies of the Egyptian figures. The eyes in both cases were inlaid, those of the lions with red jasper, white shell and blue schist: this imitation of the eyes in stone as well as metal figures was a feature common to both arts, which were at this time assuredly not without direct or indirect connexion. Whence the Egyptians and a little later on the Babylonians got their tin for the alloy we do not yet know.

The question as to whether copper really was first used in Egypt is not yet resolved, and many arguments can be brought against the theory of Egyptian origin and in favour of one in Syria or further north.26 Egypt has also recently been credited with being the inceptor of the whole "megalithic (or heliolithic, as the fashionable word now is) culture" of mankind, from Britain to China and (literally) Peru or at any rate Mexico via the Pacific Isles.27 The theory is that the achievements of the Egyptians in great stone architecture at the time of the pyramid-builders so impressed their contemporaries that they were imitated in the surrounding lands, by the Libyans and Syrians, that the fame of them was carried by the Phoenicians further afield, and that early Arab and Indian traders passed on the megalithic idea to Farther India, and thence to Polynesia and so on so that both the teocalli of Teotihuacan and Stonehenge are ultimately derived through cromlechs and dolmens innumerable from the stone pyramid of Saqqara, built by Imhotep, the architect of King Zoser, about 3100 B.C. (afterwards deified as the patron of science and architecture). This theory of Prof. Elliot Smith's is very plausible and "fascinating,"28 but whether it will prove to be true remains to be seen. The Babylonians apparently refused to be impressed by the Egyptians in this matter, and went on building temples in brick, probably for the good reason that they could not get any stone. The only stone building in southern Babylonia is the town wall of Eridu (Abu Shahrain), which is built of rude lumps of a local coral rag.29 The granites and dolerites from Magan were too fine and too expensive to build with.

Megalithic town walls were naturally common in that stone land, Palestine, and very typical specimens of them were found in the Palestine Exploration Fund's excavations at Bethshemesh ("Ain Shems") directed by Dr. Duncan Mackenzie,29 whose work also threw new light on the phenomenon of the appearance in Palestine between the 12th and 10th centuries B.C. of sub-Mycenaean (Greek) pottery, which can only be ascribed to the Philistines, whose historical position as a foreign invading force from the Aegean area (Lycia and Crete-Kaphoris) is now entirely vindicated.30 Another important excavation in Pales-

tine in the period preceding the World War was that of Dr. Reisner at Samaria, which is not yet fully published. Very interesting examples of Israelite written inscriptions on potsherds, dating from the 9th century B.C. and probably from the reign of Ahab, were found that are of great palaeographical importance.31 Continued work at Samaria should reveal some trace of the civilization of Israel, which we know was considerable, unless the devastation of the Assyrian sieges has destroyed it all. This is possibly the case with regard to the older culture of Canaan in the preceding millennium, of which Palestinian excavations have yielded few traces, though we know it existed.32 War destroyed it: Palestine was the cockpit of Asia. A more interesting discovery seems to have been made in the identification by Drs. Gardiner and Cowley of the earliest Semitic script in the hieroglyphic signs found in Sinai.33

Since the war a new British school of archaeology in Jerusalem has been founded under the direction of Prof. Garstang, who has begun for the Palestine Exploration Fund excavations at Ascalon, which have resulted in the discovery of interesting late buildings34 and this year (1921) in that of a statue of Herod the Great. It is to be hoped that continued work will discover traces of the Philistine period at Ascalon, and relics of the same age will do be discovered at Bethshan (Israel), for a time the furthest eastward outpost of the Philistines, which is about to be explored by the American School at Jerusalem. The new conditions in Palestine should be very favourable to archaeological work there, and it is to be hoped that in Syria the French will give every facility for international work.

The future of archaeological study in Mesopotamia depends upon the political conditions, which have not hitherto been considered favourable to the resumption of excavation in that country. The great German excavations at Babylon35 and Assur (Qalat Shergat)36 under the direction of Koldewey and Andrae, will probably not be resumed for many years. They were admirable work, and at Shergat especially have produced results of the greatest historical and architectural importance. We now know something of the early history of Assyria and of the succession of Mer kings from monuments found at Shergat. It is not, however, proposed to give here a list of the newly discovered names of the Babylonian kings on tablets from Nippur, published by Poebel37 and others, as results of this kind belong to the realm of history rather than to that of archaeology.

The new series of "Creation " and "Deluge" tablets from Nippur, published by Poebel & Langdon,38 also belong to the realm of the historian and anthropologist rather than to that of the archaeologist, so are merely mentioned here; the excavation in which they were found being now ancient history. In Mesopotamia more than any other country literary results have been regarded as archaeology, owing to the enormous mass of the written material recovered, which has caused the study of the art and general civilization of different periods to be neglected in comparison with the same subjects in Egypt.

In Egypt the succession to the work of the Deutsch-Orient-Gesellschaft, which excavated Babylon and Assur, has fallen to the Egypt Exploration Society, which has taken up the excavation at Tell el Amarna, where it was laid down by the Germans at the outbreak of war, after they had recovered from the house ruins several wonderfully fine examples of the art of the period of Akhenaton, now in Berlin.39 The first season's labour, under the direction of Prof. T. E. Peet, resulted in interesting discoveries, some of which tend to show that the cult of the Aten or Solardisk was not so rigidly enforced by the heretic king Akhenaton as has been supposed, and that ordinary people were allowed to worship other gods than the sun-disk, at any rate in connection with funerary ceremonies. The great excavation of the Osireion at Abydos, begun for the Society (then the Egypt Exploration Fund) by Prof. Edouard Naville,40 has been suspended owing to the war, it has not been possible to resume at present, owing to the commitments of the Amarna site and the heavy expense of such work as that at the Osireion, which cannot yet be contemplated. This building, the date of which is not yet finally settled, though its excavator believes it to be of the Old
Kingdom like the temple of the Sphinx at Giza, is one of the most remarkable in Egypt, and the completion of its excavation is much to be desired. For such a work, however, considerable funds are necessary, and all archaeological study has had to struggle along with insufficient means.

Dr. Petrie resumed operations in the Middle East after the war, and made interesting discoveries (1921). By the autumn of 1921 conditions for work were improving.

Dr. Reisner, working for Boston, was not held up by the war, but continued his excavations in the Giza pyramid field and in Nubia, making good finds in both places. His determination from the study of their pyramids at Napata (the Barkal region) of the succession of the Ethiopian kings, and his revelations of the colonial dominion of the Egyptians in Nubia under the XII. dynasty, derived from his work at Kerma and Defu, are of great importance.

Other work of importance in Nubia immediately before the war was that of Mr. Randall MacIver and Mr. Woolley for the Eckley B. Cox (Philadelphia) Expedition, which of Oxford at Farsas, directed by Mr. F. U. Griffith, which has resulted in an unreeved series of Nubian pottery from the earliest to the latest times, and that of Prof. Garstang at Merow, in the far S., which has shown us a barbaric culture of Egyptian origin, strongly influenced by the Ptolemaic and Roman civilization of its time: this is the culture of the Cynodes. The great bronze head of Augustus Caesar, now in the British Museum, is one of the trophies of this excavation, and is very interesting as being either a trophy of war carried off perhaps from Syene, or as was actually set up at Merow by the independent native rulers in honour of the Emperor. Mr. Griffith has added to our knowledge of the ancient languages of the world by his interpretation of the Merotic inscriptions, to which Prof. Sayce has also contributed.

Returning to the N. and early times again, we have to chronicle besides Reisner's excavations, those of the university of Pennsylvania (Eckley B. Cox Expedition), and of Junker for Vienna, all in the pyramid fields of the ancient state of Upper Egypt; and the middle tombs of the XII. - VI. dynasties have had interesting results. Among other important archaeological finds of the past decade are those of several new fragments of the "Palermo Stone" and similar annalistic monuments of the V. dynasty, which are of high importance for the early period. The New York Museum has further investigated the Middle Kingdom pyramid field at Lisht and its neighbourhood, and Prof. Petrie and Mr. Brunton have found fine XII. dynasty jewellery at Lahun (now in New York). At Thebes, New York has also carried out work at Qurnet Murra and Sheikh 'Abd el Qurna, as well as at Dra' Abu Nekhn, and Deir el Bahri, where the Emir was assisted by Mr. Howard Carter, and has also dug with remarkable success, recovering some of the most beautiful relics of the art of the XII. and XVIII. dynasties that we possess.

Among other tombs Lord Carnarvon has found the long-sought sepulchre of Amenhotep I. At Thebes important work in the copying of tombs has been done by Mr. and Mrs. de Garis Davies for Dr. A. L. Gardiner, who publishes with them the tombs of Amenemhet and Antefoker, under the auspices of the Egypt Exploration Society. The French Archaeological Institute at Cairo has also excavated Theban tombs, and at Dendera a naos of the XII. dynasty, with interesting sculptures of Neb-hepet Re (the king whose tomb temple at Deir el Bahri was excavated by Naville and Hall for the Egypt Exploration Fund in 1903-7) has been found, and taken to Cairo. An interesting discovery of the late period in Upper Egypt, that of images and other temple objects of precious metals, was also made at Dendera by the diggers for natron (sackah) and recovered by the "Service des Antiquités for the Cairo Museum.

Outside Egypt proper the work of editing and publishing all the Egyptian inscriptions of Sinai has been begun by Dr. Gardiner and Mr. Petrie.

A worthy completion of the record is the wonderful exhibition of all the finest examples of Egyptian art in Britain outside the British and Ashmolean Museums, held by the Burlington Fine Arts' Club in London in the summer of 1921.

ARCHAEOLOGY: GREECE AND GREEK SITES.—All important excavations which were in progress in Greek lands in 1911 came to an end with the beginning of the World War. These had not yet been resumed by 1921, partly because of the increased cost of labour, partly because of the continued inaccessibility of sites. The numerous minor excavations, however, chiefly carried on by Government authorities and local archaeologists, continued to be vigorous. The study of individual members of the foreign schools and institutions had been to some extent continued by these scholars in the course of military service with one or other of the combatant forces in the Near East.

PREHISTORIC PERIOD

The greatest advance during the decade 1910-20 was made in the knowledge of prehistoric Greece, to which increasing interest had been directed since the first discoveries of Sir Arthur Evans in Crete in 1900.

Greek Mainland.—Exploration of the Mycenaean sites of the Greek mainland has been less than was hoped for. The great painted pottery which is so plainly derived from the late Minoan wares,
there is no unbroken sequence of development such as is found at Corinthus or at Athens. The cretic civilization was not native to Greece proper, but was imposed there in a mature form upon a more backward culture. The earliest Cretan settlements in Greece belong to the end of the third Middle Minoan period (c. 1550-1400 B.C.), and it is clear that Minoan civilization had varied in different localities. The results of researches on numerous prehistoric mounds in Thessaly were exhaustively published by A. J. B. Wace and M. S. Thompson in 1912. Sites have also been explored by Xiphias, H. J. Boardman, K. E. W. (Theron) and the Ionian Islands, in Attica, at Argos, Mycenae and Tiryns, in the neighbourhood of Corinth, and in the islands of Aegina, Cythera and Rhodes. The discoveries at these sites show that Thessaly was free from Cretan or other southern influence until the late Mycenaean period and developed an isolated advanced neolithic culture until the rest of Greece and the Aegean islands were influenced by Cretan culture. Western Greece appears to have been more barbarous than Thessaly, and its outward connections, if any, before the Mycenaean period, were with Italy rather than with Greece. South-eastern Greece and the Peloponnesian show (in their sequence of pottery fabrics): (i) An Early Bronze Age culture (black-varnished ware, Ὠφήριος) similar to that of the Cyclades and Crete but of meander development, which was dominated in turn (by (ii.) a more progressive neighbours of the Cyclades (pall-paint ware, Μαμβαρδέζ) and perhaps of (iii.) Minyan ware). and ultimately (of) Crete (Mycenaean).

For the mainland cultures a new term "Helladic" has lately been invented, and the Helladic period, which includes the Hallstatt in the Helladic III period, which is subdivided into the Hallstatt (I, II, III) periods. The Helladic culture is divided into five main periods: Early Helladic (I), Early Protogeometric (II), Geometric (III), Archaic (IV), and Classical (V). The classification is based on pottery styles and the economy, which was based on agriculture and fishing. The earliest known settlement in Greece is the site of Pylaros in Phokis, which dates to the 11th century BC. The Mycenaean culture, which lasted from the 16th to the 11th century BC, was characterized by its palace architecture, rich burials, and intricate pottery designs. The Mycenaean culture had a significant influence on the Aegean region and beyond, and its collapse marked the end of the Bronze Age in the Aegean.

The period is marked by significant cultural and economic developments. The Mycenaean civilization was characterized by its advanced craftsmanship, including pottery, metalworking, and architecture. The construction of large palaces, such as that at Mycenae, was a hallmark of the period. The Mycenaean culture also had a significant impact on the development of later Greek culture, including the development of the Greek alphabet and the foundation of the city-state system.

The Mycenaean period ended with the collapse of the Mycenaean civilization, which is believed to have been caused by a combination of environmental, economic, and social factors. The collapse of the Mycenaean civilization is thought to have contributed to the rise of the Geometric period, which is characterized by a renewed interest in the arts and crafts, as well as a focus on agricultural and economic development.
Greece.—There has been most archaeological activity at Athens, where its results have been mainly topographical. The cemetery of Kerameikos was questioned, and an excavation undertaken in 1911. Another excavation was in progress in 1914. A search for the Odeion of Pericles on the south-east slope of the Acropolis was inconclusive. Some pieces of sculpture were found here, among them fragments of the Parthenon frieze, and another group of architectural sculpture. They were of the 5th century B.C. or even earlier. A group of these sculptures was displayed in the Museum of Athens. The Parthenon frieze was published by the Athenian Archaeological Institute in 1912.

Thessaly.—A sculptor from Thessaly was murdered by a gang of robbers at the time of the 1914 war. The sculptor was found in a painted sarcophagus. He was a native of Thessaly. The sculptor was buried with a magnificent collection of silver from the 5th century B.C. and a gold ring from the 4th century B.C. The tomb was opened by the Thessalian authorities in 1914.

Asia Minor.—Political conditions in Asia Minor were greatly affected by the 1914 war. The political situation was marked by a series of treaties and conventions. One of the most important was the Treaty of London, which was signed in 1914. This treaty settled the Greek claim to the Dodecanese Islands. The Greek government was forced to yield to the pressure of the Turks, who were strongly opposed to the treaty. The Greeks were allowed to retain certain islands, but they were not able to obtain the islands they had been promised. The treaty was signed by the Sultan of Turkey and the Greek government. The treaty was ratified by the Greek parliament in 1914.

South Russia.—The sites of the colonies in South Russia used to be a copious source of Greek antiquities of all periods, but the supply has ceased at the present time. From 1911 to 1914 Kerch (Panticapaeum), Old and New Chersonesos, Tanaïs, Oltia, a town on the Danube, were among the most important sites. A great number of valuable finds were made here. The finds were rich in fine bronzes of the 4th century B.C. and the 3rd century B.C. A remarkable glass bowl with coloured reliefs, said to be Alexandrian work, was found at Oltia in 1913. A glass cup with reliefs carved in the blue and white technique of the Corinthian style was found at Chersonesos in 1913. The tomb of a scythian royal grave in a tumulus at Solokha, in 1913. The burial was richly furnished with barbaric jewellery, a gold comb, a bow-case and some vases decorated with Greco-Scythian reliefs. The discovery of a large number of valuable bronzes at the site of Kerch, which has long lain inaccessible in Russian books and periodicals, was published by E. H. Minas, in 1913.

Greek Islands.—Among the Greek Islands Corinth has produced the most notable find. At Corinth, the ancient Coryce, in 1811, the Greek Archaeological Society discovered an early archaic temple of Artemis, the excavation of which was continued until 1914 by the British School, on the expense of the former Emperor of Germany. The striking feature of the building is the sculpture of the west pediment, carved in high relief on limestone slabs. The subjects are, between two pannels, a central group of a giant Melissa with her two children, and a group of another Melissa, on one side, and a group of a woman and two children, on the other. The sculptures are in an apparently unconnected battle scene. A large altar stood before the west front. The small Ionic temple at Kardaki in Corinth was excavated in 1912. The French have made good progress in their excavations in the Roman cities of Heliopolis and Phalera. The Tomb of Pompeii, its houses still preserving their mosaic floors and fresco-painted walls. When Mytilene was recovered by the Greeks it was found that the buildings were still in a good state of preservation. The restoration of the eastern group has been proposed (F. Courby, 1914). A popular but scholarly account of Delphi was translated into English from the Danish of F. Poulsen in 1914.

In 1914, the excavation of the cemetery of the ancient city was resumed after the war up to 1914; the last finds in 1914 were two colossal portrait statues of members of the Julio-Claudian family, perhaps Caius and Lucius Caesar. The excavation of Delphi was one of the most important in the world, and the finds were of the highest importance. The excavations at Delphi continued in 1914, and the publication of the discoveries, made in 1892, was still unfinished. Among other details, the interior arrangements of the temple were studied, and it was established that there was no natural material in the temple, which is the subject of an important work by F. Courby. The Parthenon was rediscovered, and, as in the other temples, an archaic temple was discovered. The excavators were able to claim that the archaic temple was itself. The pediment sculptures were reconsidered with fresh interest, as they showed a remarkable amount of interest in the animal forms. The southern part of the temple was excavated, and the material has continued to be published. The excavation of the eastern group has been proposed (F. Courby, 1914). A popular but scholarly account of Delphi was translated into English from the Danish of F. Poulsen in 1914.
excavators began by driving a level platform from the river bank towards the acropolis on the line of the ancient temple of Apollo, which had had to be removed by the increasing mass of soil, for the mountain had been washed down to the river in a continuous slope. A hundred metres from the columns they struck the west end of a temple, which was subsequently called the Hera temple. A century later, when the covering of soil became deeper, the temple, which (as inscriptions show) was dedicated to Artemis, had been half-buried by a landslip from the acropolis hill in the historic earthquake of 17 A.D. It is a matter of conjecture whether new inscriptions were obliterated or not, but finished at the time of the earthquake, then cleared and partially rebuilt, and finally used as a water reservoir in the Byzantine period. At the west end, to which the temple belonged, the steps are still preserved to the height of 30 feet. Great efforts were made to remove the deep deposit of earth from the surrounding precinct, and the temple now stands in a wide, open space. The temple, with its foundation-plates, is in a perfect condition, the high, progress was checked by a solid mass of the hill which had come near to wreathing the building altogether, having finished its slide less than 100 ft. from the portico. This mass had buried a great part of the Lydian and Greek temples, but on a protected slope some undisturbed Lydian strata were found. Here the pottery sequence goes back through sub-Mycenaean wares to simpler geometric and plain black and grey fabrics. These provide means for classifying the rich finds from the sanctuary of Apollo, which were excavated on the site of the ancient temple of Apollo, just as it is necessary to know the sequence of geologic strata in the study of architecture. These are all of the highest quality. Many bronze mirrors were found. The local pottery is marked in form by a conical base, in technique by a white slip, like the archaic Greek wares of Athens. The finds are of the latest archaic and early classical styles. The most of the pottery in the temple was found in a general deposit, and a large number of inscriptions, the most valuable being two bilingual texts, in Lydian-Aramaic and Lydian-Greek. These have not, however, given the basis of a Lydian style at Ephesus as was contended by some Greeks. The inscription which was found in the temple of the temple of Artemis at Ephesus indicates that the temple was derived from Lydian. Annual reports of the excavations were published in the American Journal of Archaeology.

The temple of Zeus was excavated on a terrace of the acropolis; the date of the earliest repairs goes back to the Hellenic settlement, to the 11th century B.C. In one of three Greek temples excavated at Locri were the temples of Apollo and Artemis and two of the temples of other gods and spirits, and some exceptionally fine bronze mirrors.

Etruria.—A few temples of Etruria were founded at Veii in 1310 B.C., and from an Etruscan tomb at Todi some inscriptions were discovered which are partly bilingual and partly in Etruscan, describing the names of prominent Etruscan leaders.

A temple of Zeus was excavated on the terrace of the acropolis; the date of the earliest repairs goes back to the Hellenic settlement, to the 11th century B.C. ARCHITECTURE (see 2:395).—United Kingdom.—The years 1910-4 were years of great building activity in England. Money was plentiful and only faint rumbles of the impending storm of labour troubles were heard. Many of the recently incorporated municipalities, whose activities were constantly increasing and were hampered by the inadequacy of the old borough council offices to accommodate their increasing staffs, were desirous of obtaining municipal buildings worthy of their civic dignity. The large commercial firms were meditating building new offices of ever-increasing splendour, and the newly enriched, who always had the ambition to possess land and become county magnates, were planning palatial residences for their newly acquired estates. The war put a stop to all new activities with the exception of those that were connected with the war effort. The war had, however, so delayed the many projects that were contemplated. So many years had elapsed since the last great European war that its effects had been forgotten. In fact, opinions were by no means at one as to the effect of war on the arts generally. On the one hand there is no doubt that in the ancient and mediaeval monarchies and republics the arts flourished vigorously during the stirring times when these states were consolidating their power by conquest, some of their finest works having been erected as records in stone of victories over their enemies and their cities having been embellished with
ARCHITECTURE

objects of art taken as spoils from the vanquished. On the other hand it may be argued that a lengthy peace, when man's energies lack the outlet which war provides, may tend to turn those energies in quite other directions and cause an outburst of exuberant originality—too often mistaken for genius—in all the arts that almost inevitably leads to such a decadence as is evidenced in the "Dada" poetry, futurist and cubist painting and the bizarre extravagances of the late Baroque style of architecture.

But war as waged by the ancients or in fact down to the end of the 19th century was a very different thing from what it is now. In the early part of last century the opinion was growing that war was in course of being modified, softened and civilized, made—as Leigh Hunt says—a thing of courtesy and consideration. Now, however, "frightfulness" is the predominating idea in war. The perfection of modern engineering skill, the enormously increased calibre and range of modern artillery, the conquest of the air as a medium for rapid transport and a fierce velocity of attack never before dreamed of have resulted in a completeness of material devastation that must be seen to be realized. In France alone during the World War 250,000 buildings, including 1,500 schools, 1,200 churches and 377 public buildings, were destroyed so completely that no restoration was possible; while the enormous cost of modern warfare impoverishes all the combatants to such an extent that the spoils which used to go to the victors and be employed in adorning their cities are non-existent.

These are the direct effects of war on the creative arts of man, and the indirect effects are no less harmful. The dragging away from their usual peaceful pursuits of all the workers, and the consequent necessity of restricting the output of everything but what is needed for carrying on the war, puts a stop to all constructive effort of an artistic kind. This restriction continues afterwards partly through the scarcity of materials and partly through the moralization of labour caused by war.

War Buildings.—It seems clear therefore that modern war must have a crippling effect on the arts of peace, especially with regard to architecture. Statistics show that in the first nine months of the year 1914 building plans were submitted for approval to local authorities in England involving an outlay of £12,200,000, whereas in the same period of 1913 the figures were only £5,870,000, out of which as much as £3,000,000 was for temporary workshops and factories for war materials. These buildings, and others of a temporary character for housing the largely increased staff of Government employees—the cost of which in London alone in the year 1916 was £5,56,000—were practically the only structures which the British Government allowed to be proceeded with during the last three years of the war. In these temporary buildings celerity in construction was the great desideratum, the materials used being of a non-permanent character, such as wood treated with solignum, uralite and asbestos boarding, variety being obtained by breaking the line of frontage and varying the sky line by a judicious alternation of hipped and gabled roofs. In some cases, however, a more elaborate scheme was adopted, involving a carefully planned lay-out and variety in the treatment and grouping of the buildings, which resulted in a picturesque architectural effect. The most important of these special groups of buildings carried out by the Government was at Gretna, where was built the largest explosives factory in the world. Here the factory proper was in two portions separated by an area within which was located the accommodation for the operatives during construction and for the permanent workers. The site chosen for this township—for such it was—providing for about 20,000 inhabitants, was close to the old Gretna Green village, within easy distance of two railway stations, the new accommodation roads linking up with the main road from Carlisle to Glasgow. The buildings comprised no less than five churches, ten schools, three recreation halls, hospitals, cinemas, and fire stations in addition to the houses. The work was carried out under the general direction of Raymond Unwin, assisted by several other architects, and the whole scheme reflects great credit on all who were associated with it.

A similar but smaller building scheme was carried out during the war at Chestew, where a site of 28 acres was acquired for the employees of Finch & Co.'s engineering and shipbuilding works. This site offered considerable difficulties in that there was a fall of 88 ft. from one end to the other, but this irregularity has resulted in the creation of a very picturesque village. The houses, which numbered ten to the acre, are of various sizes planned to meet the requirements of individual families, the walls being constructed of two solid 4-in. blocks of concrete separated by an air cavity of three inches.

Among buildings specially connected with the modern developments of war may be mentioned those for the construction and housing of non-rigid airships. At the commencement of the war Great Britain possessed only six of these buildings, but 61 have been constructed since. Although of no particular architectural interest the large size of these buildings renders them worth a passing notice. Mr. Learmonth states that one of these buildings covers about 8 ac. in area, is 750 ft. long, 130 ft. in height and each bay has a clear roof span of 150 ft.

Post-war Housing.—One of the most interesting developments of post-war building on the part of the British Government was in connexion with land settlement for ex-service men provided for by the Land Settlement (Facilities) Act of 1919. Up to 1914 the various county councils had been empowered to raise local loans for the purpose of providing small holdings under the Small Holdings and Allotments Act of 1908. This work was suspended during the war, and after its termination the Ministry of Agriculture purchased estates and conducted extensive building operations all over the country, the settlement at Sutton Bridge in Lincs. being the most important. The work subsequently devolved on the county councils under the supervision of the Ministry. Between Jan., 1919 and the spring of 1921 upwards of 13,500 small holdings have been erected in England and Wales, consisting of a homestead and farm buildings, involving already an expenditure of over £2,000,000. It was hoped eventually to accommodate over 30,000 settlers. Local materials are used in the construction, and these naturally influence their style. There is not naturally much scope for architectural display, but the planning and aspect of the rooms always receive careful attention. The Ministry placed the supervision of this work in the hands of competent architects under Maj. H. P. Maule.

The cessation of building during the war caused a great shortage of houses, and a large number of housing schemes were started under the Housing Act of 1919 (see HOUSING). Garden cities, garden villages and garden suburbs sprang up in all directions. One of the most important features in these new schemes was the limitation of the number of houses to the acre, only twelve being allowed as a rule in urban and eight in rural districts. This is a great improvement on the earlier garden cities, where the close proximity of the houses practically destroys all privacy. It is impossible however to lay out a site on this lavish scale in urban districts where slum property has been demolished and the occupants have to be housed in tenements. In such cases, with three-storey blocks properly separated from one another, perfect hygienic conditions can be obtained, with ample fresh air and sunlight, if there are 60 separate tenements to the acre. Among the rural housing schemes started after the war may be mentioned that near Woolwich carried out by H.M. Office of Works, the Borough of Croydon housing schemes at Norbury, Woolwich and Waltham, the Welwyn Garden City, and the interesting village at Burhill, near Walton on the Thames, for aged men and women workers. This was erected in accordance with the provisions of the will of the late William Whiteley, and comprises a village hall, a church and about 300 cottages. Sir Aston Webb, Sir Ernest George, Sir R. Blomfield and other eminent architects collaborated in the scheme.

The urban tenement schemes comprise those at St. Pancras, which were in course of being carried out in 1921, at Islington and St. Marylebone. The much increased cost of building made it very difficult to carry out these schemes on an economic basis.

Churches.—The completion of the interior of Bentley's remarkable Roman Catholic cathedral at Westminster progressed
Fig. 1.—Woodworth Building, New York.
Fig. 2.—Lincoln Memorial, Washington.
Fig. 3.—Carmelite Convent, Santa Clara, Cal.
Fig. 4.—Nebraska State Capitol, Lincoln, Neb.
but slowly during 1910-20. Some of the mosaics of the side chapels had been finished by 1921, but very little had been done with the pavements, for which the architect prepared many beautiful designs worked out with the most meticulous detail both of form and colour; if these designs are eventually carried out the marble mosaic floor will not suffer in comparison with the best of the older examples.

The Liverpool cathedral by G. Gilbert Scott, which was much delayed during the war, was making fair progress in 1921, and when completed will be a most interesting example of modern Gothic, and from its commanding position, it will be a striking monumental building as seen from the Mersey. That Gothic still holds its own for ecclesiastical buildings is shown by many modern churches, of which St. Mark's, Walsall, by the late Temple Moore, one of the greatest of the modern Gothicists, and a church at Gretna by Geoffrey Lucas, may be taken as types.

**Municipal Buildings.**—Among municipal buildings the enormous London County Hall on the south side of the river was approaching completion in 1921; the Marylebone town hall by Cooper and the offices of the Metropolitan Water Board by Austen Hall had been completed, and the large building for the Port of London offices occupying a commanding site on Tower Hill was well advanced.

**Commercial.**—Among recent commercial buildings one of the most noteworthy is the Cunard building at Liverpool by Willink and Thicknesse. This is one of three important buildings on the site of the former slums, and with wide spaces all round it, opposite the landing-stage, occupying the position of a small dock that had been reclaimed from the estuary and was closed in the year 1900. The Italian Renaissance style was adopted for this building, the total length of which is 350 ft., and the average breadth 183 ft., the height above the pavement being 120 feet. The building is constructed of reinforced concrete faced with Portland stone rock-faced, heavily rusticated and battered up to the first-floor level and with dressed Portland stone above, the first and second floors forming a piano nobile. A very heavy cornice projecting about 7 ft. from the wall faces the building and above this is a screen wall about 10 ft. high. It is a matter of regret that there is a lack of harmony in the elevations of the three buildings on this splendid site. Other large commercial London buildings recently completed in 1921 were the Wolseley Motor Car offices in Piccadilly, by Curtis Green; Australia House in the Strand, by Marshall Mackenzie & Son; and the Kodak building in Kingsway, by Sir John Burnet, which, in its unadorned severity is an excellent example of the proper way to treat a skeleton steel structure.

Street architecture in the business centre of a town offers to the architect one of the most difficult problems with which he has to deal. The sites are almost impossible to disfigure the mind of the ordinary large retail tradesman of the idée fixe that the more space he has for outside show of the articles he deals in, the better it is for his business. The consequence is that in most cases the architect has to start his design on the first floor and to all appearances to carry his structure on a thin plate of glass on the ground floor. This is of course fatal to good architecture. Fortunately the idea has been growing—though very slowly—that a more artistic and alluring display of goods can be made if the various articles are framed in panels separated by bold structural piers of stone. Among the best of recent shop fronts in London treated architecturally from top to bottom may be mentioned the Selfridge building in Oxford Street, and Messrs. Heal's premises in Tottenham Court Road. In these buildings the supports of the superstructure are carried down through the ground floor.

The decade 1910-20 saw the commencement of the passing of the Regent Street which had been familiar to Londoners for over a hundred years. Whatever may be thought of stucco design in imitation of stone, there can be no doubt that Nash achieved a really fine effect in the façades of this street, which were dignified, unassuming and free from monotony, and one cannot regret a feeling of regret to see these old fronts replaced by lofty new buildings which, whatever their individual merits may be, do not seem likely to group together so as to give the street an effect of architectural congruity.

**Factories.**—The effect of their daily surroundings on the workers in factories has been the subject of careful attention. Anyone who knows the majority of the old mills and factories in the Manchester district, with their tall brick walls and square windows with no attempt to break their hideous uniformity, cannot but be impressed with the horribly depressing effect which these buildings must have upon those who are employed in them. The planning of factories now demands almost as much care as the design for a hospital. Ample light, preferably from the north, is provided and variegated glazed-brick linings are used for the walls of the work-rooms to break their monotony, the junction of the walls and floors being rounded off to avoid dust accumulating. Mess-rooms and changing-rooms are provided and in these are often placed separate lock-up clothes lockers for each female worker. Employers have begun to recognize the fact that expenditure on these refinements is well repaid by a greatly increased output from the employees.

As another example of the way in which the welfare of employees is cared for may be instanced a building recently erected in Gower Street as a hostel for the female employees of a firm of drapers. Included in this building, which contains about 350 bedrooms, are a lounge, reading-room and library and a large hall with stage for concerts and amateur theatrical performances. This marks an interesting new departure in what may be called domestic commercial buildings.

A considerable amount of discussion has taken place as to the desirability of removing the restriction laid down by the London County Council that no building shall be erected of a greater height than 80 ft. from the pavement, exclusive of two storeys in the roof, and allowing sky-scrapers on the lines of those in New York. Granted the existence of an open space of sufficient extent on all sides, there would be no harm in erecting a building 200 or 250 ft. high, but unfortunately where high buildings are most urgently required is in the congested area of the city and here the situation would result in a complete overshadowing of the lower buildings, which would entirely destroy their amenities and practically render them unusable except by artificial light. Any general relaxation of the restrictions is to be deprecated, but in exceptional positions there is no doubt that the rules might be modified with advantage.

**Domestic.**—Domestic architecture, in which England has always excelled, came almost to a standstill during 1910-20, mainly owing to the enormous cost of building. Among recent examples may be mentioned Heath Lodge, Headley Common, by Dawber; a very picturesque house in Avenue Road, St. John's Wood, by Baillie Scott; a house near Goring, a typical example of Ernest Newton's refined work; and a house at Shotton Mill, Surrey, by E. J. May.

**Memorials.**—War memorials are of various kinds; isolated monuments such as crosses and obelisks; shrines or chantry chapels added to a church; mural tablets; and occasionally what may be called a utilitarian building erected as a memorial but only indirectly associated with those whose deaths are memorialized. The number of these erected all over the United Kingdom as well as in France and Belgium is so great that it is impossible to mention more than a few. Among the isolated monuments the Apprentice House in Whitchurch, which, for dignity and simplicity combined, cannot easily be surpassed; the all-India memorial at Delhi (see DELHI) by the same architect will be one of the most important features of the new capital of India. Sir R. Blomfield has designed a number of memorial crosses, of which it may be said that the bigger the scale on which they are executed the better is their effect. A very graceful example of a memorial cross is one at King's Lynn by O. P. Milne which stands on a large pedestal on the sides of which are engraved in panels the names of those who fell in the war.

The War Memorial Chapel in Ely cathedral by Dawber; the memorial screen and organ designed for Merton College chapel, Oxford, by Sir R. Lorimer, which shows the Gothic tradition still
surviving; the Memorial Gateway at Radley College by Sir T. G. Jackson; the Lliford Memorial Hall at Broadway, the Marlborough College Memorial Hall by Ernest Newton & Sons and the Kitchener Memorial Chapel in St. Paul's cathedral may be instanced as good examples of other types.

Mural tablets do not call for much remark; the chief things to be aimed at in these are good lettering and judicious spacing, many of these tablets being far too crowded. An ornate example of these in cast bronze enriched with precious stones is the Regimental War Memorial to the King's Own Yorkshire Light Infantry in York minster by Voysey.

Architectural Education.—A generation ago no systematized scheme of architectural training existed in England. In Paris an Academy of Architecture was established as long ago as 1671, and thereafter was generally recognized that the training of architects all over France in the 18th century was largely due to the supervision which that academy exercised over the training of young architects. The foundation of the Ecole des Beaux Arts in the beginning of the 19th century carried on the work of the academy, and the institution of the Grand Prix de Rome—the blue ribbon of the architectural student, the training for which is spread over from ten to fourteen years and the gaining of which ensured official recognition—offered an incentive to hard work and study which had most beneficial results. In Great Britain until the establishment by the Royal Institute of British Architects in 1837 under Royal Charter of a compulsory examination for all who wished to become members of that body, architectural education was of the most haphazard kind. The new charter empowered the institute to grant certificates and diplomas to those who passed its examinations, and although this policy met with some opposition at first, there can be no doubt that it laid the foundation for systematized architectural education, the full effect of which has only been realized during the last decade. This has been brought about by the increase in the numbers of provincial universities unharnpered by old traditions. These bodies, following the lead of similar institutions in the United States, have all recognized the fact that architecture, which is both an art and a science, may fitly be included in the subjects of study for a university degree. In addition to the universities several technical colleges have instituted courses of study in architecture, and there were in 1921 in the United Kingdom ten schools of architecture which were recognized by the Royal Institute and whose certificates exempt those students who gain from them its examinations. These schools are the Architectural Association, London; the universities of London, Liverpool, Sheffield, and Manchester; the Robert Gordon Technical College, Aberdeen; the Technical College, Cardiff; the Heriot-Watt College, Edinburgh; and the Glasgow School of Architecture. The university of Cambridge has established a school of architectural studies, but the examination in the subjects comprised in the school curriculum is not associated at present with any diploma; the R.I.B.A., however, exempts certificated students from a certain part of its obligatory examinations.

In Liverpool a special degree in architecture (B. Arch.) has been instituted, but the other universities named include architecture as one of the subjects for an Arts degree. The Liverpool course—which may be taken as a typical one—extends over five years and comprises design in accordance with the methods of the Ecole des Beaux Arts; the history of architecture; physics; geology; sanitation and hygiene; building construction and strength of materials as demonstrated in laboratory tests; specifications, etc. Similar courses slightly varying in detail are given at the other schools. In the university of London (University College) a separate professorship of town planning has been instituted. The Architectural Association, London—which was really the pioneer in architectural education in this country—has a very comprehensive course under a complete staff of lecturers, and the studios and class-rooms in its new premises in Bedford Square are admirably equipped.

All these courses enable the young architect to acquire not only facility in design, but also the special technical knowledge now required in consequence of the development of steel construction, and the fact that so many engineering problems are involved in the erection of any large building; and as all the degree courses involve the passing of a matriculation examination which ensures that the student has first obtained a good general education, one may confidently hope that the approach so often levelled against architects of a lack of scholarly training is in a fair way of being removed.

Architectural Research.—No record of recent architectural developments could be complete without reference to the researches of Mr. J. Hammond of New York on the scale of proportion adopted by the Greeks in the design of their most celebrated temples. These must have been designed on some plan, but hitherto all attempts to discover any relation between length and breadth, or between length and height, of the Parthenon or any of the temples which Mr. J. Hammond claims to have established the fact that whereas down to the first quarter of the 6th century B.C. Greek craftsmen used a unit of measurement in which commensurability of line was an essential feature; subsequently a new proportion came into use based on commensurability of area; and this he calls "dynamic" symmetry as opposed to static; in other words geometric and not arithmetic proportion.

There is always a danger of a pet theory becoming a sort of Procrustes bed to which facts have to be strained to fit, but Mr. J. Hammond has certainly taken great pains to avoid this by having numerous measurements taken independently and checked.

Mr. J. Hammond's theory may be described briefly as follows: The diagonal of a right-angled triangle of which one side is unity and the other 2 is \(\sqrt{5}\), or 2:236.

In fig. 1, \(a b = 1\), and \(b c = 2\), so that \(a c = \sqrt{5}\); if we make \(a d = a e\) and \(d e = 1\) and complete the rectangle \(a d e f\), this will be a \(\sqrt{5}\) rectangle made up of a square \(d g\), and two rectangles \(g k\) and \(e f\) each of which is \(\sqrt{5}^{-1} = 0.618\). Mr. J. Hammond maintains that in the Temple of Apollo at Bassae designed by Ictinus the proportions are based on this rectangle and its multiples and submultiples. In the case of the Parthenon a more elaborate basis is adopted; in fig. 2 \(a b c d\) is a \(\sqrt{5}\) rectangle and if its long side be taken as unity the short side will be 0.447. If to a \(d\) the long side of this rectangle is added, the new rectangle \(a b c d\) is a \(\sqrt{5}\) rectangle of which one side is 1 and the other 1.447. The reciprocal of this latter figure is \(1 = 0.691\) and if we apply to the rectangle \(e f g h\) the area of which is 0.691 we shall obtain a large rectangle \(b e g d\) the area of which is 2.138, which comprises a rectangle \(e b f c\) whose area is 1.447 and a smaller one \(e f g h\) of area 0.691. This last rectangle is in all respects similar to \(e b f c\) and if \(g f = e f\) then \(f g = g e\) will be a square and \(b e g a\) a \(\sqrt{5}\) rectangle.

Now whatever we may think of this somewhat elaborate basis of measurement it is remarkable how many cases the ratios connected with the figures 2:138, 1:447 and 0.691 fit within very small fractions of actual measurements of the Parthenon, which, as well as the temple at Bassae, was designed by Ictinus. For example the actual breadth over all of the base of the Parthenon according to Pernice is 111.541 ft. and this figure multiplied by 2:138 gives 238.069 as the length, the actual measurement so far as can now be ascertained being 238'154, a variation of less than one inch.

Mr. J. Hammond has applied this theory to Greek statues and vases and—as he claims—the same results. Those who are interested in the subject may be referred to two papers read before the Royal Institute of British Architects on March 30 1920 and March 5 1921.

The prospect for architectural development in the immediate future was not altogether a bright one in 1921. Although many building schemes both in London and the Provinces were ripe for execution, our spending power was far from adequate owing to the enormous cost of building and uncertainty as to the action of Labour. Also official architecture was spreading. Large Govern-
ARCHITECTURE 187

ment departments, which used to invite competitive designs for their new buildings with excellent results, were increasingly tending to prepare their own designs. This must lead to a stereotyped style and is not in the best interest of architecture or architects. Design—as far as plan is concerned—has undoubtedly improved immensely, but as to the style which will be adopted for future buildings prophecy would be rash. In 1830 Quatremère de Quincy, in the preface to his Biographie des plus célèbres Architectes, uses these words: “Comme nous ne révols de véritable art d'architecture que celui qui . . . a dû son origine, ses progrès, ses principes, ses lois, sa théorie et sa pratique aux Grecs . . . nous devons prêter qu'on ne trouvera dans notre recueil aucune notion d'aucun ouvrage du genre appelé Gothique.” This seems to be the rule of modern criticism. The art is attended by some of the most beautiful examples of mediaeval art, but ignored them utterly, and yet 25 years later the Gothic revival was in full swing. In 1900 Penrose said that it was impossible to find any one who took the slightest interest in Greek architecture, yet a few years later Neo-Grec and a bastard sort of classic was all the rage in England, while in America many of the finest new buildings are in the pure classic style. Now a free renaissance is in vogue, but how long it will last and what will be its developments no one can tell. The hope is that the complication of modern requirements and the exigencies of modern construction combined with wider knowledge and closer study of ancient examples may lead to the working-out of the great main principles which underlie all the old styles, so as to adapt them to modern necessities without sacrificing copying of their forms and features. (J. St.)

UNITED STATES

The Centennial Exposition in Philadelphia (1876) had revealed to a somewhat self-centred and self-satisfied United States the flagrant grossness of its current architecture; the Chicago World’s Fair (1893) less than 20 years later disclosed both the possibilities of architecture and the capacity of a new generation of architects. Its influence was widespread so far as the public was concerned, and gave architects themselves new ideals and greater confidence. From 1890 to 1900 the architectural product of the United States was vast in bulk and high in quality. The American Institute of Architects (founded in 1857) broadened its scope and influence, while schools of architecture associated with universities and technical institutes offered wide opportunities for architectural education. The results were evident in the first decade of the 20th century. The Boston Public Library and the Rhode Island State Capitol of McKim, Mead and White were the forerunners and inspiration of many other structures of similar nature and quality. The New York Public Library of Carrère and Hastings and the Minnesota State Capitol of Cass Gilbert being the most notable. In the same category must be ranked many of the club houses of New York, notably the Union and University, as well as sumptuous residences in the larger cities and summer resorts. The Gothic revival, largely determined by Henry Vaughan and Cram, Goodhue and Ferguson, was meanwhile taking to itself practically the whole field of church building and the larger part of college architecture. Beginning with the Episcopal Church, the adoption of Gothic of some English type (usually Perpendicular) extended throughout the United States until within 20 years Presbyterians, Congregationalists, and Unitarians were also erecting consistent and magnificent Gothic churches. From the work of Cope and Stewardson at Princeton University the same influence spread through the institutions of higher learning, until Tudor or “Collegiate Gothic,” as it is called, usurped almost the whole field, though the “McKim Classic” of Columbia and the revived Colonial of Harvard and many of the smaller colleges and schools still maintained themselves as potent forces and in the latter cases a growing force. The rivalry of Classic and Gothic played little part in the two fields of work where American architecture achieved its most vital and original results, the “sky-scraper” and the private house. Steel and reinforced concrete are, as structural elements in buildings, essentially American. Used at first as substitutes or hidden devices clothed with traditional architectural forms, they subsequently developed and established what may be called a “steel frame style.” Many daring experiments led the way, including Cass Gilbert, who in the Woolworth Building produced a masterpiece. All the great cities (except Boston which prohibits “sky-scrapers”) possess many examples of this brilliant and original work, and in New York in particular there is an extraordinary display of towers. By 1920, however, there were signs that the vogue of 50-storey buildings was passing, and probably would take its place in history as a brief but sensational episode that brought out some of the most daring exploits, and gave play to the most exuberant fancy, in the architectural record. At the opposite pole stood the domestic architecture of the 20th century. Between 1850 and 1880 this had fallen to the lowest depths, and the influence of H. H. Richardson, distorted after his death by incompetent imitators, was deplorable. Fortunately there came a sudden return to the Colonial models of the 18th century, together with a new study of the domestic buildings of England of the 15th and 16th centuries; and though at first the adaptations were crude and unintelligent, the improvement was rapid, and an extraordinary level of excellence was achieved. No one exerted a wider influence in this direction than Charles A. Platt. So vast was the architectural product of the United States during the first 15 years of the century, that it would be impossible to catalogue all the examples of the highest excellence. Among the more distinguished public buildings, in addition to those noted, should be included Henry Bacon’s masterly Lincoln Memorial in Washington and B. G. Goodhue’s revolutionary design for the Nebraska Capitol. In this field, however, politics were apt to enter with disastrous effects, as for example in the Pennsylvania Capitol. In the work of the national, Government there was a serious retrogression during 1910-20, and Government architecture was in grave danger of slipping back to the deplorably low level of the 20 years following the Civil War. Where the political element was eliminated, public architecture achieved a high standard, particularly noticeable in art galleries, libraries and museums. Amongst the first were the Buffalo gallery by Green and Wicks, that at Minneapolis by McKim, Mead and White, and that at Boston by Guy Lowell. One of the most admirable of recent libraries was in Indianapolis, the work of Paul Cret and Zantzinger, Borie and Medary, associate architects, while the Pan-American Building in Washington, by Albert Kelsey and Paul Cret, was an unusual example of vital and personal design. Close ly allied were many fine club houses such as the Grand Army Hall in Pittsburgh by Henry Hornbostel, and the Masonic Temple of the Scottish Rite in Washington by John Russell Pope, a building of strikingly noble proportions and majesty of design. In all these buildings classical motives were general, but they were handled with suppleness and originality. Such structures as the Indianapolis library and the Scottish Rite Temple in Washington, D.C., evinced a vital and creative art. Many buildings for universities and colleges, and for schools both public and private, showed equal freedom based on penetrating knowledge of precedents, though the models were almost exclusively English Tudor or American Colonial. Cope and Stewardson initiated the vogue of the former at Princeton, continuing it at Bryn Mawr, Pa., and at Washington University, St. Louis, and it swept the whole eastern part of the country. Cram, Goodhue, and Ferguson took up the line of development in the vast, fortress-like U.S. Military Academy at West Point and continued it at Princeton in the Graduate College, as well as in other educational institutions, north and south. Day and Klauder gave it new force in the Sage dormitories and freshman dining halls at Princeton, in the new buildings at Cornell University, and at Wellesley College, while James Gamble Rogers contributed the most magnificent exposition of the style in the enormous quadrangle nearing completion in 1930 at Yale. Colonial work achieved notable results at Harvard in the shape of new dormitories by Coolidge and Shatsock, but it was more prevalent in the smaller colleges and preparatory schools, as for instance, Williams College and Phillips Academy, Exeter, where the architects worked
along English Georgian lines in the one case, New England Colonial in the other. With the recovery of the delicate proportions and grave simplicity of the early American style, quite distinct in character from contemporary work in England, and style became almost fixed as the standard type for the eastern states, in public and private schools, a result in great measure due to the influence of E. M. Wheelwright. In the Middle West the Tudor motive, popularized by W. B. Itter in many public schools, held the field; in the south and on the Pacific coast the early style of the Franciscan missions, sometimes touched by Italian influence, was admirably adapted to modern and local conditions by such architects as the Allisons of Los Angeles; while in Texas, Rice Institute was being worked out by Cran & Ferguson in a curious style with no particular prototype but epitomizing the blend of Mediterranean impulses, the principal effects being attained by combination of coloured marbles and iridescent tiles.

Church building during the period 1910-20 was exceedingly active. Cathedrals, both Roman Catholic and Episcopal, some rivalling in size those of France and England, were building in many places. Amongst the former were the great Byzantine cathedral of St. Louis, Barnett, Haynes and Barnett architects, and that in St. Paul by Paul Masqueray. The Episcopalian cathedral, still under way in 1921 in Washington, an immense structure in Decorated Gothic, was designed from the plans which were made by the late George F. Bodley of London, and Bernard Vanbrugh. B. G. Goodhue’s Baltimore cathedral promised to be an original and vivid adaptation of English Gothic, while the cathedral of St. John the Divine in New York must, when completed, take rank as the third in size of the cathedrals of the world. Begun in 1801 by Heins and La Farge in a modified Romanesque, it was continued by other architects in an adaptation of the French Gothic of the 13th century, though diverging widely from the standard type. The latter architects also built the bishop’s palace, deanery and synod house for the same see, as well as the cathedral in Detroit. The parish churches, both Roman Catholic and Episcopal, were many in the order of high style; it is doubtful if anywhere a loftier standard had been attained. Roman Catholic architecture in the United States, until after 1900, was of a debased quality, even worse perhaps than that of the Protestant denominations. By 1920 such work as that of Maginnis and Walsh in St. Catherine’s, Somerville, Mass.; the convent of Notre Dame in Boston, and that of the Carmelites in California; and John T. Comer’s churches of St. Agnes, Cleveland, St. Mary’s, McKeepsport, Pa., and St. Monica’s, Rochester, N.Y.; also St. Agnes’, Pittsburgh, Pa., restored the balance, a result due almost wholly to these architects. An example of the Catholic architecture at its best was B. G. Goodhue’s Dominican Church of St. Vincent Ferrer in New York, a model for the Episcopalian church, St. Thomas’s and the Church of the Intercession in New York, both designed by Cram, Goodhue & Ferguson, were indicative of the advance made in the 10 years ending with 1920 toward developing a style which should at the same time preserve the best traditions of Christian art and be mobile in its adaptability to modern times and conditions. Apart from the Christian Scientists, who built widely during the same period and usually in a form of Classic closely allied with that of the standard type of Carnegie library, the Protestant trend has been largely towards Gothic of one sort or another. More and more the new work approached the standards, methods and forms of Catholic art, as for example in Allen and Collens’s Congregational church in Newton and the Fourth Presbyterian church in Chicago by Cram, Goodhue and Ferguson and Howard Shaw. Occasionally remarkable re-creations of Colonial work were achieved, chiefly for Congregationalists and Unitarians. The Baptists, Methodists and Lutherans showed only sporadically an inclination towards higher standards, and in the south and south-west deplorably inferior structures were still produced. The Swedeborgians always stood for high architectural ideals and were well served during his lifetime by Prof. Langford Warren. They built at Bryn Athyn, Pa., a “cathedral” which was closely modelled on the lines of the richest type of a large English parish church of the early 15th century. Here for in America the architects (Cram and Ferguson) undertook to put into practice the old “guild” methods of building of the Middle Ages.

With its vast area, its widely varying climatic conditions, its many racial strains, and its groups of independent traditions, the United States has produced as varied an assortment of domestic architecture as might have been expected. Some of the notable palaces of New York and the fine villas set in beautiful gardens and parks in attractive country areas rival the most splendid examples of the Italian, French or English Renaissance, not only in their architecture but in their priceless collections of art of every kind. It is in the more modest dwellings of those not in the multi-millionaire class that recent architecture has scored its greatest triumph. American architects have always been adept at housing, and American inventors ingenious in developing new conveniences and luxuries of domestic life. Now that the standard of style has been established and steadily maintained, it may be claimed that the American dwelling equals if it does not surpass all its competitors. The most notable schools of this period were those of Philadelphia, the Middle West, New England and the Pacific coast. The first was initiated by Wilson Ayre, Frank Miles Day and Cope and Stewardson, of whom only the first was alive and working in 1920. But they were followed by a large group of younger men, and the results were striking in originality, consistency and taste. With the local Colonial style as a basis, something was added from the best modern English revival of Tudor architecture, something from the subtle Georgian of Mr. Platt, something from the Italianesque of Mr. McKim, though the dominant note still remained essentially Pennsylvanian. Colour, detail, texture all played their part in a romantic yet honest expression of domesticity, and so universal was its acceptance that even the speculative builder employed the best exponents of this style to develop whole communities along consistent lines. It would be impossible to name all the men who created this significant expression of the best in modern American domestic architecture, but Robert McGoldwin, together with Mellor, Meigs and Howe, Willing and Simms, Edward Gilkes, and Duhring, Okie and Ziegler, may be mentioned. In the Middle West, there were two tendencies, one with a mathematical basis, the other almost purely poetic. The first seems to have been started by Louis Sullivan, with his strange and vivid motifs in geometrical decoration. Frank Lloyd Wright continued and developed this along extraordinary lines with an exaggeration of horizontal elements that seem to have grown out of decorative forms rather than from material requirements. Claude Bragdon and Pond & Pond also contributed to this movement. The other tendency in the Middle West was best represented by Howard Shaw, who was much influenced by the pure beauty of the 15th century French and Japanese work, and by certain new trends in the arts, notably the Assarain group, but those who have tried to make the most of the influences of that group have not always been modest. The principle of the 15th century was the avoidance of heavy ground plans, the use of free and simple space relations, the avoidance of the picturesque. The work of the Assarain group was as a rule experimental, and so far as it went it was progressive in so far as it went it was progressive in a general sense. It was not so much a reaction against the Gothic of the 15th century as a reaction against the Gothic of the 19th century, and, as such, it was perhaps more interesting than it was useful. In the later years of the 19th century the 15th century Gothic architecture of England and France was much admired in England, and the work of the Assarain group was often little more than a reaction against the Gothic of the 19th century, and, as such, it was perhaps more interesting than it was useful. In the later years of the 19th century the 15th century Gothic architecture of England and France was much admired in England, and the work of the Assarain group was often little more than a reaction against the Gothic of the 19th century, and, as such, it was perhaps more interesting than it was useful.
In 1913 another traverse was made through the heart of Greenland by Capt. J. P. de Koch, Dr. A. Wegener and a Danish seaman. After a winter on the E. coast near Danish Harbour, during which they had found the land ice had thickened to 20 ft. with ponies to drag their sledges, and reached Lake Fjord on Aug. 1. The greatest alt., on the crossing was 9,500 ft.

The second Thule expedition was led by K. Rasmussen in 1916 for the exploration of Greenland, for which he was accompanied by Lauge Koch, Dr. Thorild Wulff, H. Olsen and several Eskimos. After an arduous journey of over 700 m. across the mouth of Greely Fjord, where work was started in the neighbourhood of St. George Fjord, Surveys were carried out on Long Fjord, where they linked up with previous work of Peary. On the return journey Dr. Wulff and Olsen succumbed to the privation of scanty food and harsh climate, and both died before reaching the Thule, Tuktoyaktuk. This expedition found that Nordenskjold Fjord, the supposed western end of Peary Channel, is only 14 m. long. The inland ice in the N.W. of Greenland was found to extend nearly to the coast; conclusion based on the hunting and movements of Eskimo migration. Rasmussen considered it very doubtful if Eskimo ever succeeded in reaching the E. coast via the N. of Greenland.

A third Thule expedition started in 1920 under the leadership of Lauge Koch, who proposed to explore the interior of Peary Land and to find in certain gaps in the chart of the N.W. coast of Greenland, and its exploration established a number of points in Inglefield Gulf, and it was expected to stay in the field until 1922.

The American Crocker Land expedition, from its base at Etah, surveyed part of the coast between Etah and Hall Basin in 1913-14, and by an aerial survey on parts of Foulke Fjord. Its principal work, however, was in Ellesmere Land.

The American Crocker Land Expedition.—This expedition was sent in 1913 by the American Geographical Society and other bodies in the United States to search for Crocker Land, which had been reported by Peary in 1906 as lying to the W. of Grant Land.

D. B. MacMillan, the leader, had, with him W. E. Eklaw and M. C. Tanquay, naturalists, and J. F. Green, cartographer. Failing to reach either Pin L. or Flower Bay in Ellesmere Land, with the three successful expeditions which had been established at Etah, there was a meteorological station was maintained throughout the duration of the expedition. In March 1913 MacMillan and Green crossed Smith Sound on the ice, traced Ellesmere Land and, assisted by information from the Sound, reached Cape Thomas Hubbard. Thence a journey N.W. over rough sea ice for 150 m. failed to reveal any trace of land, and the party returned to Etah by the same route. The farthest point reached was lat. 82° 30' N., long. 168° 22' 30" W. The members of this expedition made several other long journeys. In 1916 Eklaw crossed Ellesmere Land from Cape Sabine to Bay Fjord and, passing by Cape Thomas Hubbard, reached Lake Fjord, Greedy's former station on Robeson Channel. He returned to Etah across Kennedy Channel and along the shores of Kane Basin. The same year MacMillan made a long journey to Amund Ringnes Fjord and Christian Fjord, discovering a large bay on the coast of Ellesmere Land from Cape Sabine to Clarence Head, which considerably altered the charts based on the rough surveys of Inglefield, Kane and Hayes. Several expeditions were sent to relieve the explorers at Etah, but the first in 1915 met with disaster, and had to winter in North Star Bay; the second in 1916 failed to get through Melville Bay, but the third in 1917 brought back safely those members of the expedition who had not previously returned via the Danish settlements in Greenland.

Beaufort Sea.—Much exploration has been done in and around the Beaufort Sea, although the greater part of that sea is still a blank on our maps.

The ambitious Anglo-American polar expedition of 1906–7 achieved relatively little real polar work except a journey from March to May 1907 by E. de K. Leffingwell, E. Mikkelsen, and S. Sabine, during which they crossed the Arctic Ocean from the coast of Greenland to the eastern slope of the Hayes Range on lat. 72° 9' 33" N., long. 149° 44' 42" W. where they got a sounding of no bottom in 620 fathoms. V. Steffansson, who was nominally a member of the expedition, spent his time with the Eskimo in the Mackenzie delta, learning their habits and language and in order to equip himself for future explorations. During 1908–12 V. Steffansson and R. M. Anderson were studying the Eskimo in and around Victoria I., where they discovered the so-called blonde Eskimo, who had never before been encountered. Observations and conclusions must be attributed largely to his methods. He lived in Eskimo fashion using only Eskimo diet, which enabled him to travel light and avoid fatigue. A suitable outfit for a season in Foyn's region have been employed with equal success by Rasmussen and other Danes in Greenland.

In July 1913 Steffansson sailed from Nome with a large expedition, supported by the Canadian Government, for the exploration of the Beaufort Sea and the N.W. shores of Arctic Canada. Capt. R. A. Bartlett was in command of the chief ship, the "Karlik,"
ARCTIC REGIONS

and the scientific staff included I. Murray, R. M. Anderson and F. J. Murray, G. M. Halsey, J. P. O'Neill, geologists; H. Bouchez and D. Jennes, anthropologists; W. McBenkin and B. M. McDonell, meteorologists; and Dr. Forbes Mackay, surgeon. The "Karlik," with most of the northern party on board, continued the survey of the ice north of the 70° 30' parallel. In the ice north of the 70° 30' parallel. The vessel drifted W. until, Sept. 20, when Stefansson and several men ashore hunting, broke away during a heavy gale, drifted with them and sank in lat. 73° 8' N., long. 175° 50' W., 60 m. E. N. E. of Herald I., on Jan. 11 1914. All hands and ample stores were got safely on the ice. After the loss of the reconnitering party south, Baclott decided to await the return of another ship, making it clear that use of Stefansson, Bouchez and a sailor, eager to attempt the journey, set off for the land, with Bartlett’s permission but contrary to his advice. They were seen some days later and never heard of again. On March 29, a group landed on the island, led by Baclott, accompanied by an Eskimo and his crew and seven dogs, set out for the mainland, 160 m. across the ice, to seek help. He reached the shores of Siberia in 17 days, and traveling along the coast via Cape North, reached Emma Harbour, whence he crossed in a whaler to St. Michael. The "King and King " rescued the survivors on Wrangel I., and the "Bear" brought them to Nome. Mame and another man had died on the way, and remained of the expedition, employing several small sloops, did a great deal of useful work. Stefansson, with two companions and a dog team, left Martin Point, Alaska, on March 22 1914, reached lat. 65° 30' N., and then for 13 days to Cape Prince Alfred on June 26 and joining his vessel at Keellett. In Feb. 1915 with three companions, Stefansson reached Prince Patrick I., and completed the charts of the coast. Pushing on through the remaining islands in the vicinity of the Adolph Sea, reaching this island, and discovered a second smaller island N. of Elfin Ringnes I., and a third, small, E. of the first and N. of Melville Island. Stefansson, with two companions, R. G. Leech, and Christian I. was found to be much smaller than had been supposed. Much survey work was also done in Banks I., Victoria I. and the coasts of Dolphin and Union Straits. In 1918 a severe attack of fever beset the remaining men who had returned to have two crossing seasons’ work’s season’s work to S. Storkerens, Storkerens, setting out from Cross I. on the coast of Alaska, travelled over the sea ice to lat. 73° 38' N., long. 147° 59' W. and then returned to the mainland. This journey probably from the mainland, then (1918) reported vaguely in the "seventies of last century," while soundings being taken during the drift of the "Karlik " and other journeys of the expedition have now continued, and prob- ably of land existing in the western part of Davis Strait.

On the other hand a sounding of only 275 fathoms, about 100 m. N.W. of Isachsen I., indicates the possible occurrence of land in the eastern part of that sea, although Crocker Land has been ruled out to be a myth. Stefansson’s expedition also brought back many observations in anthropology and geography.

Russian Expeditions—Several ambitious but ill-equipped Russian expeditions were sent out in the Arctic regions. They accomplished little or nothing. G. L. Sedoff hoped to make Franz Josef Land a base for a march to the Pole. He left Archangel in the Phoca and wintered at Punkateiv I. in the N. of Novaya Zemly (1908). After (replacement of the Phoca by the Kororin") reached Hooker I., Franz Josef Land. Sedoff set out for the Pole with two companions and 24 dogs. On the death of the leader of the expedition, the dog sloop, was abandoned. G. L. Brusilov sailed in July 1912 to attempt the north-east passage in the "Santa Anna." The vessel was beset in the ice in the Kara Sea in lat. 71° N. and drifted a year and a half to the vicinity of Franz Josef Land. Eleven men left the ship in April 1914 in lat. 81° 76' N., long. 65° E. Two of these reached Cape Flora, where the "Phoca" found them; the others perished on the way. Nothing has since been heard of the ship and the remainder of its crew. V. A. Rusavov in the "Hercules" was last heard of in 1912 in Matochkin Shar on his way to the Kara Sea on a voyage of exploration. The Russian Government in 1914 sent the "Eclipse " under Otto L. Møller to search for Rusavov, and passed through the Kara Sea searching the coast eastward to Tajmir Land where he wintered in lat. 74° 45' N., long. 92° E. He was able to be of some service to Vilikitsky’s expedition wintering about 180° S., but before his return had to give up the search for the "Hercules." He returned to the Kara Sea in Sept. 1915 without having found any trace of the missing expeditions.

Russian efforts to explore the N. coast of Asia in ice-breakers were far more successful, but unfortunately there is every likelihood that their reports have been exaggerated. Captain R. H. Atwood was accompanied by thirty men in 1913 on a voyage of the island of Marble having been lost. The "Taimir" and "Vaigach," which Capt. Sergey had taken from Petropavlovsk to near Cape Chelyuskin in July 1913 for the Comm. of B. A. Vilikitski and Comm. P. A. Novgorodov, was employed for an hydrographic survey of the Arctic coast of Siberia. After charting Chum Bay the vessels separated, the "Vaigach" following the coast westward and the "Taimir" for the Novgorodov Islands. The island was discovered E. of this group and named Vilikitski Island. Bennett I. was found to be much smaller than had been supposed, and so no sign of Samilov Land (reported on more than one occasion to have been seen from Kotelnoi, New Siberia I.) was found. Samilov Land was reached in 1913, and continued the coast survey. New land was discovered N.W. of Cape Chelyuskin. Nikolais Land extends from lat. 77° 50' N., long. 99° E., to at least lat. 81° N. It was surveyed on the east side of the Bay, and the rest of the island, the remainder of which was named Taimir, Starodomskoye, each with a greatest width of about 6 miles. The easiest way of these lands is to account for the usual obstruction of pack-ice in the waters of the Nordenskjöld Archipelago and the Kara Sea. The vessels being anchored near the mouth of the Taimir River, the entrance to the Sea of Okhotsk was examined, but the entrance to the Sea of Okhotsk was examined, but the entrance to the Okhotsk Sea, the "Taimir " and the "Vaigach" having left the Kara Sea in lat. 55° 13' E. The vessels got clear of the ice, and pro- ceeded early in Aug. passed through the Kara Sea without encountering, and reached Archangel in Sept. 1915.

Roald Amundsen.—The long-deferred expedition of Roald Amundsen to the polar basin left Norway in June 1910 in the "Maud," built on an improved model of the "Fram.

The first winter was passed near Cape Chelyuskin. From there two men were sent home with dispatches via Siberia, but have not since been heard of again. In Sept., 1911, having completed his voyage through the melted Nordenskjöld Sea and Flatte Strait. East of the New Siberia I. Amundsen pushed his vessel into the pack in order to begin his drift across the Arctic Ocean, but found that the current was stronger than he had anticipated (1911) for the year, and sought winter quarters at Aion I., Chau Bay. In July 1920 he arrived at Nome in Alaska having completed the north-east passage. Soon after he left for the north he resumed his original plan of arriving in Russia, having the happy experience of having the country of Spitsbergen and Bear I. on Norway. All the islands of the Ameri- can Arctic Archipelago are claimed by Canada.

Waters,” Videnskabs. Selskabets Skrifter No. 2 (Kristiania 1915), contains oceanographical investigations in the Barents and Greenland seas.

ARDILAUN, ARTHUR EDWARD GUINNESS, 1st Baron (1840–1915), Irish philanthropist and politician, was born at St. Anne’s, Clontarf, Nov. 1, 1840, the eldest son of Sir Benjamin Lee Guinness, 1st bart., head of the famous brewing firm of Guinness. He was educated at Eton and Trinity College, Dublin, and in 1868 succeeded to the baronetcy on the death of his father. He then became head of the firm of Guinness, but shortly afterwards retired. He entered Parliament in 1874 as Conservative member for the city of Dublin, holding the seat till 1886, when he was raised to the peerage. In 1891 he bought St. Stephen’s Green, Dublin, and converted it into a charming park, which he presented to the city. He also bought up various blocks of sham dwellings and converted them into model tenements, with the object of improving the conditions of the poorer classes of Dublin. Lord Ardilaun, who married in 1871 Lady Olivia White, daughter of the 3rd Earl of Bantry, died at Clontarf Jan. 20, 1915.

ARENSKY, ANTON STEPHANOVITCH (1861–1906), Russian musical composer, was born at Novgorod July 31, 1861, and after studying with various teachers finally became a pupil of Rimsky-Korsakov at the conservatoire of St. Petersburg. In 1882 he became a professor at the Moscow conservatoire, and from 1894 to 1905 was director of music in the imperial chapel at St. Petersburg. His works consist largely of chamber music, including the well-known trio, besides several operas, the chief of which are The Dream on the Volga (1890), Roi Shaph (1894), and Nal and Domoyandi (1899). He died at Terioki, Finland, Feb. 25, 1906.

ARGENTINA (see 2,450).—The pop. of the republic in 1920, according to the census made by the Census Bureau, was 8,533,431. The latest census which had then been taken, that of 1914, gave the pop. at that time as 7,885,237, indicating an increase during 1914–9 of 646,194, or 8.2%. The pop. of the political divisions was as follows—

**Total:** 8,698,516

The pop. of the chief cities, according to the latest statistics available, was as follows—

- **Buenos Aires:** 1,668,072
- **Rosario:** 222,502
- **Córdoba:** 156,000
- **La Plata:** 105,990
- **Tucumán:** 39,974
- **San Juan:** 51,191
- **Mendoza:** 38,790
- **Bahía Blanca:** 44,413

**Paraná:** 36,089
**Corrientes:** 28,681
**Salta:** 28,436

The nationalities most largely represented in the pop., according to the census of 1914, were—

- **Argentines:** 5,527,285
- **Italians:** 928,893
- **Spaniards:** 829,701
- **Russians:** 93,534
- **Uruguayans:** 154,128
- **French:** 79,191
- **Turks (mostly Syrians):** 64,639
- **British:** 27,692
- **Germans:** 26,696
- **Swiss:** 14,345
- **Portuguese:** 14,143

There were also about 15,000 Indians and 500 negroes then in Argentina.

**Agricultural and Mineral Production.**—The total area under cultivation in Argentina was 20,367,082 hectares (50,336,066 ac.) in the season 1910–11 and 24,784,602 hectares (61,218,463 ac.) in the season 1911–12, an increase of 10,819,587 ac., or 21.6%. The area under the principal crops for the season 1911–12 was—

The development of cotton-growing in Argentina is especially noticeable, the area under cultivation having increased from 879 hectares in 1893 to 3,500 in 1911 and 17,275 for the 1917–8 crop. The Government has devoted much time and money to its development and has sent young men to the United States to study cotton-growing. Exports of wheat totalled 2,966,460 tons in 1918, maize 664,685 tons, oats 543,976 tons and linseed 394,382 tons, lack of shipping preventing greater exports. These figures may be compared with those for 1905 when 3,815,240 tons of wheat (more than ever before), 1,607,650 tons of linseed (also more than ever before), 1,711,804 tons of maize and 440,011 tons of oats were exported.

Argentina was in 1920 the world’s largest exporter of linseed and maize (Indian corn), and third in exports of wheat, being only exceeded in the latter commodity by the United States and Canada. Her crop nearly equalled Canada’s for several years preceding 1921. It has been estimated that approximately 80% of the soil of the republic is capable of yielding some form of economic return, but that only about a quarter of such land was in 1920 under any form of cultivation, while practically no part of Argentina is under intensive husbandry. Agricultural education in its various phases greatly progressed in Argentina during the 10 years 1910–20 under the guidance of Dr. José Léon Suárez in respect of national education and under such local leaders as Dr. Juan B. Terran at Tucumán in the provinces. The inauguration of the university of Tucumán in May 1914 and the development of its instruction in the production of sugar, cotton and other products suited to northern Argentina has been of great benefit to a large section of the country.

In 1917 there were 860 creameries, 470 cheese factories, 27 butter factories and 680 "mixed" establishments, the export of cheese having increased greatly during the World War. There were 408 flour mills, capitalized at $36,933,659. Most of these were in the provinces of Buenos Aires, Santa Fé and Córdoba. Exports of wheat flour increased from 118,486 tons in 1911 to 176,445 tons in 1918. Argentina produces approximately 35,000 bales annually of wool and there are 14 wool-washing establishments in the country. There were 29 breweries in 1914, and 4,663 establishments for the production of wine in 1917. The wine industry centres in the provinces of Mendoza and San Juan.
The output of all the packing and curing houses in 1914 was $114,960,886. The petroleum output at Comodoro Rivadavia increased from 14,784 kg. in 1907 to 198,672,698 kg. in 1918.

Foreign Commerce.—The imports and exports for the years 1914–8 are shown in the following table:

Although Germany ranked second after Great Britain in imports into Argentina in 1913, her trade sank to practically nothing during the World War; it has since shown signs of increasing. The chief articles Imported by Argentina are cottons and woolens, iron and steel, hardware, machinery; railway equipment of all kinds, lumber and coal. The chief exports are agricultural: wheat, maize, linseed oil, oats, wool, and meats, chiefly beef and mutton. The customs receipts were $19,795,729 in 1913; $12,135,528 in 1914; $9,991,660 in 1915; $10,726,226 in 1916 and $9,080,114 in 1917. The commercial depression which began about the middle of 1920 proved very injurious to Argentine foreign trade, curtailing both imports and exports.

Finance.—The expenditure and revenue in Argentina for the years 1915–20 are shown in the following table, the amounts being in pounds sterling:

The 1919 and 1920 figures are budget estimates.

Railways.—Argentina in 1920 was tenth among the nations of the world and third among American nations in respect of her railway mileage. In 1910 the total was 17,403 m.; in 1915, 21,551 m.; and in 1920, 21,015 m.

Army and Navy.—The estimated military budget for 1920 was £3,000,000 and the naval budget £2,004,611. The total peace establishment of the army was in 1920 approximately 1,751 officers and 18,000 men. In addition there was a trained reserve of 300,000 men, 150,000 of whom were of the first line, and 150,000 of the special reserve. A territorial reserve was in process of formation. The navy consisted of two Dreadnoughts, two pre-Dreadnoughts, four armoured cruisers, and one old light cruiser. There were also seven destroyers, being with the Dreadnoughts the only modern units in the Argentine navy. The Dreadnoughts “Moreno” and “Rivadavia” were built in the United States and launched in 1917. Their displacement is 27,910 tons each and their nominal speed 22.5 knots. The personnel of the navy included 316 executive and 97 engineer officers, 23 electrical engineers, and from 5,000 to 6,000 men. There was also a coast artillery corps of 4,200 men.

The addition of the “Rivadavia” and the “Moreno” to the Argentine navy was by far the most important event in its development since 1910. Since 1914 the German influences in the Argentine army have somewhat abated with the return of the German military instructors to Europe. Both the army and the navy seemed in 1920 to turn more toward British, French and U.S. methods; no less than 23 naval officers were in that year undergoing instruction in the United States.

History.—The administration of President José P. Ignacio Alcorta came to an end Oct. 12, 1920, when the inauguration of Roque Saenz Pena took place. Although early in 1910 an attempt had been made to conduct a campaign on behalf of Guiller- n° Udaondo, former governor of the province of Buenos Aires, as an opposition candidate to Saenz Peña, this movement did not develop much strength and Saenz Peña was elected without opposition. He was the son of Luis Saenz Peña, who had been President from 1892 to 1895, but was of more cosmopolitan type, having spent much time in the Argentine diplomatic service, in both Europe and America. Victoriino de la Plaza, who had been Minister of Foreign Affairs in the administration of Figueroa Alcorta, now became Vice-President. His long residence in England as Argentina’s financial representative had placed him in close touch with sources of foreign investment which meant much to Argentina, and had given him a sympathetic point of view as regards foreign interests and affairs. Saenz Peña’s Cabinet was a strong one. Dr. Indalecio Gomez, who had been Argentine minister to Germany, was Minister of the Interior and continued in this office throughout Saenz Peña’s administration, while the Ministry of Foreign Affairs was filled by Dr. Ernesto Bosch, who had also been in the diplomatic service. Saenz Peña had no less than four Secretaries of the Treasury, beginning with Dr. Jose Maria Rosa, who had put Argentina’s finances on a sound basis when Minister of the Treasury in Roca’s administration in 1899 and possessed much knowledge of financial affairs. His successors were E. S. Perez, Norberto Pinero and Lorenzo An- don. Dr. Juan M. Garro and Dr. Carlos Ibarquen were Saenz Peña’s Ministers of Public Instruction and Worship, Gen. Gregorio Velez and Rear-Adm. Saenz Valente holding the War and Naval portfolios in turn. In the latter capacity the latter has been responsible both for the Navy portfolio, which continued to be held by Adm. Saenz Valente, and the National Railways. The Ministry of Public Works and the Ministry of Agriculture are filled by Adm. Marcos Mejia, who had been in the Cabinet in the previous Administration, and Carlos Meyer were the Ministers of Public Works, and Adolfo Mujica Minister of Agriculture.

President Roque Saenz Peña died Aug. 9, 1914, Vice-President de la Plaza succeeding him. An entirely new Cabinet, except for the Navy portfolio, which continued to be held by Adm. Saenz Valente, came into office Aug. 9, 1914. Manuel Ortiz became Minister of the Interior; José Luis Murature, who had long been an editor of La Nacion, one of the most prominent Buenos Aires newspapers, was minister of Foreign Affairs and Worship; Manuel Moyana Minister of Public Works; Horacio Calderon Minister of Agriculture; and Gen. Angel P. Altairia Minister of War. The Treasury portfolio was held successively by Dr. Alejandro Carbo and by Dr. E. E. Oliver, and that of Justice and Public Instruction by T. R. Cullen and M. E. Lamas. The period of de la Plaza’s presidency almost exactly coincided with the first two years of the World War. When it broke out England stood first in Argentine foreign trade, with Germany a close second. The English also led in the amount of foreign capital invested in Argentina, although French and German investments were also considerable. Through his term of office President de la Plaza maintained an attitude of strict neutrality on behalf of his country, though his personal preference and certain of his official acts showed an inclination toward the Allies.

In 1916, when de la Plaza’s successor was to be chosen, divisions in the old Government party, which had been so long in power under various names, made it powerless to prevent the nomination and election of the candidate of the Radical party, Hipólito Irigoyen, who had never before held public office. For the first time in Argentine history the Radical party was in control of the Government and for the aristocrats (from whose ranks almost all the higher officials had been chosen) it substituted as members of the Cabinet either politicians of their own party or practical business men, such as Domingo Salaverry, the able Minister of the Treasury. Although the Ministry of Foreign Affairs and Worship was nominally filled, first by Dr. Carlos A. Becu, who resigned Feb. 3, 1917, and then by Honorio Pueyrredon, who had previously been Minister of Agriculture, the able young Under-Secretary, Diego Luis Molinari, who had travelled in the United States and Europe, practically directed the actual management of Argentina’s foreign relations during the first five years of Irigoyen’s administration. Pueyrredon was not formally made Minister of Foreign Affairs until Sept. 13, 1918.
Interior Department was directed by Dr. Ramón Gómez throughout
outside Irioyen’s term, the Ministry of Justice and Public In-
struction by José S. Salinas, and that of Public Works by Pablo
Torelo. For the first time in the history of Argentina the
Ministry of War was held by civilians, Dr. Elpidio González
(until 1918) and his successor Dr. Julio Moreno. An engineer
of some distinction, Federico Álvarez de Toledo, was Minister
of Marine until his resignation in 1919, when Julio Moreno
was entrusted with the Navy portfolio also. After Pueyrredón left
the Ministry of Agriculture in 1917 Alfredo Demarchi, an engineer,
assumed charge of that Department. The Vice-President, Dr.
Pelagio B. Luna, from the province of La Rioja, who was sup-
posed to represent the Radical influence in the interior of the
country, died June 25, 1919. Benito Villanueva then became
president of the Senate and therefore next in succession to the
presidency, although he did not cease to be the President’s
political party. The elections in 1919 strengthened the hold of
the President and the Radical party over both Houses of Con-
gress and gave the Radicals reason to hope that they would
continue in power and win the 1922 presidential elections, in
spite of differences of opinion among some of the leaders in
the party and the inevitable disputes as to who should be the
candidate.

With the entry of the United States into the World War in
April 1917, the attitude of Argentina, like that of many other
Latin-American countries, was divided, one section pining
desired a rupture of relations with Germany, while another
believed that Argentina’s future position of independence should
be safeguarded by a strict neutrality. The general mass of the
population was strongly in sympathy with the Allies, with the
natural exception of the 26,000 German subjects and the 40,000
persons of other German origin. Their influence was particu-
larly strong in Argentina because of the excellent German organiza-
tion there and because of the feebleness of the Allied propaganda
until the war was nearly over. For some time after the outbreak
of the war in 1914 it had been feared that all the skilled workers
and other immigrants of the better classes would return to
their native lands; and during 1917, 1918 and 1919 44,285 more
persons did leave the country as steerage passengers than entered
at the same time the cost of living rapidly advanced, and there
was a corresponding spread of social unrest, partly due to the
popular feeling that the President had espoused the cause of
labour and so was disposed to listen sympathetically to the
claims of the various labour organizations. This attitude brought
him into conflict with the English-owned railways, which com-
prised 74% of the railways of Argentina, and did not discourage
the Spanish-speaking countries of 1917, which were supposed to have been
instigated by German agents. The most disastrous of these was
the general railway strike which paralyzed traffic throughout
the country from Sept. 23 to Oct. 17, 1917. Moreover, labour
agitations and strikes of all kinds continued to develop in all parts
of the country. They distracted public attention from
international to local issues.

On Sunday, Sept. 8 1917, the Buenos Aires newspapers
published certain cablégrams which had been sent in May
and June 1917 by the German Minister at Buenos Aires, Count
Luzburg, to the German Foreign Office, in one of which he said:
"Argentina has been the first of Germany’s ships, I advise that they be compelled
to go back or that they be sunk without leaving any trace
(sepulros versenkt) or not allowed to pass." Four Argentine
merchant vessels, the "Orina," "Monte Protegido," "Toro" and
"Curumanal," were sunk by the Germans. The publication of
these cablégrams caused great excitement in Buenos Aires and
four days later, on Sept. 12, Honorio Pueyrredón, the acting
Minister of Foreign Affairs, notified Luxembourg that he was
persona non grata to the Argentine Government. Pueyrredón had
been personally offended by Luxembourg’s allusion to him as a
"notorious ass" in the published telegrams. On the evening of
the same day a large mob destroyed the largest German club in
Buenos Aires, attacked the premises of the three pro-German
newspapers and seriously damaged a number of German business
establishments. Popular indignation was increased by the opera-
tion of a high-powered German radiograph station near Buenos
Aires designed to communicate with Nauen, near Berlin. Pam-
phlets and leaflets were circulated telling of German designs on
South America. Intense excitement reigned in the Argentine
capital, and on Sept. 19 the Argentine Senate voted by 23 to 1 in
favour of breaking diplomatic relations with the Central
States. On Sept. 24 the Chamber of Deputies voted a like resolution by
53 to 18. A large number of senators and other prominent persons
took part in a large and significant pro-Ally parade on Sept. 20, which
was one of the most notable demonstrations in the history of
Buenos Aires. In spite of all this anti-German manifestation,
however, the President maintained an attitude of strict neutrality
and the German legation continued to function in Buenos
Aires under Count Donhoff as chargé d’affaires, while German
intrigues in Argentina continued unabated, spreading thence
throughout Latin America. But a large number of volunteers
joined the Allied armies, and all the Argentine communities gave
freely to Allied Red Cross and relief funds.

Education.—The following table gives the amounts appro-
priated for Education in 1910, 1915 and 1920 in U.S. dollars.

ARGONNE, BATTLES IN THE, 1914-6.—On Sept. 29 1914 at
early dawn the advanced guards of the French II. Army Corps
left Ste. Menehould with orders to reach Grandpré the same day.
The II. Corps was en route, about half a day’s march ahead of
the IV. Army Corps, which was on its left, and of the left corps of
the III. Army on its right. At about 12 o’clock one of the
advanced guards of the II. Corps carried, by a forced attack, the
village of St. Thomas, a kind of natural fortress dominating
the valley of the Biesme. A German staff officer was killed, on
whom was found an order of the IV. German Army commanding them
to hold the fortified positions marked by La Justice (2 km.
south of Cerny), hills 147 and 148, height 140 (between Servon
and Pailerolles), hill 152 (south of Cerny) and Salines (200 ft.
above the valley). In the evening of the 14th the French Colonial Corps was stopped
by the resistance of the enemy at Ville-sur-Tourbe; the II. Corps
carried Servon, but, isolated by the delay of the III. Army
and the check to the Colonial Corps, it could not emerge therefrom.
It may be said that on the evening of Sept. 14 mobile warfare ceased in
Argonne and trench warfare began.

The German staff had left the valley of the Biesme to take up
its positions farther back; this decision seems to have been
speedily regretted, for on the morning of the 17th great efforts
were made by the Germans to regain the heights dominating the
Biesme. The French forces tried at first to continue their north
ward march, but they soon felt the uselessness of their efforts.
Then position warfare was accepted, but so regretfully that
immobility was found difficult to observe; time was wasted, and,
in war, time is blood. Nevertheless, the return towards the
Biesme attempted by the Germans as early as Sept. 15 had not
yet been completely successful by July 1918, at which moment the
débâcle for Germany began. On Sept. 15 1914 the Germans
retook Servon, but could not debouch from it. Their efforts to
do so remained fruitless during the whole of the war.

Further eastwards the II. Corps in various attempts to reach
Binarville. The Germans retook the south edge of that village
and gained ground in the woods of La Grue; but they came up
against the most tenacious resistance and were never able to
seize Vienne-le-Château, of which they did not leave a stone
standing. More to the east obstinate fighting took place all through the winter of 1914 and the spring of 1915 at Bagatelle, a small ruined hunting-box. Bagatelle fell into the hands of the Germans, but although the latter penetrated into the woods as far as La Harasze, they were unable to cross the Biesme there. The right of the IV. Army was at a spot called St. Hubert, near the Meurissons stream which ends at Le Four de Paris. Le Four de Paris was under the authority of the III. Army, commanded by Gen. Sarrail. The V. Army Corps, left of the III. Army, had not been so rapid in its pursuit as the II. Corps; the liaison of the two armies could, therefore, not take place, as had been planned and was desirable, at the crossing-point of La Vielle Chese on the Haute Chevreuchel; the crossing-point was taken by the Germans. On Sept. 23 and 24 the V. Corps, which had succeeded in reaching Montblainville, gave way, lost Varennes and allowed the enemy to approach Meurissons and Le Four de Paris.

On Sept. 20 the XVI. German Corps attacked La Chalade, Le Four de Paris and La Harasze simultaneously, and reached the vicinity of the Biesme. It must be noted that, at that time, Gen. von Strantz’s army forced the Haunts de Meuse, entered St. Mihel, seized Fort Camp des Romains, crossed the Meuse and endeavoured to advance westwards, beyond Chauvonnour. This was the development of Verdun, by St. Mihel and by the Biesme, and was the most critical period of the struggle in 1914. But on Sept. 30 the German 98th was taken by surprise near La Chalade, two of its battalions being completely destroyed, or nearly so. The Germans were driven back to and beyond St. Hubert. Furious fighting went on at Bois de Bolante, La Fille Morte, and Courtes-Chavres. From Oct. 6 the front was practically fixed in these parts.

On Nov. 20, 1914 the 70th Div. of the French V. Corps, which was under Gen. Gouraud, became attached to the II. Corps. General Gérard, commanding the II. Corps, then became the real commander of Argonne, while the German facing him was Gen. von Mudra. On Jan. 5, 1915 Gen. Gouraud made a successful attack at Courtes-Chavres.

The Germans had been greatly assisted, at the outset, by a special trench-warfare matériel from Metz. On the French side the matériel and special mine-warfare units had to be improvised. During the winter of 1914-15 there were no projectiles even for the guns, and those manufactured in haste made the British 75-mm. guns explode.

Shortly after the II. Corps had settled in Argonne the French general-in-chief shifted the limits of the armies. The Aisne marked the right of the IV. Army, commanded by Gen. de Langé de Cary, and the left of the III. Army, under Gen. Sarrail, whose headquarters were at Ste. Menchoulot. Ste. Menchoulot on one side and Varennes on the other were the fountain-head of all orders. Gen. Sarrail in the south, the German Crown Prince in the north, organized the combat that was more often sacrifices. The Aisne in the west, the Oise and the Verdun region in the east, were the limits of that bloody battle-field where the fighting was conducted in woods, in trenches which were little more than streams, owing to the extreme dampness of the soil. The men were dying from cold and frost, not from order, that seems to have been the rule. It was to be tedious to enumerate the units, both large and small, that passed through Argonne, won fame and wore themselves out. Nevertheless, mention must be made of the Garibaldi brothers and their legionaries, who, with heroic courage, showed the Germans that a fierce assault that Italian steel is as good as its men.

General Gérard was replaced, on Jan. 15, 1915, by Gen. Humbert. The latter was appointed commander of the III. Army, after Gen. Sarrail’s reverse, in the month of July 1915.

By the month of Feb. 1916 Verdun had become the centre of the gigantic struggle; Argonne was never quite calm, but the fighting there henceforth took the second place; large numbers of men were no longer sacrificed at the outset. The armaments balanced little by little and, in Argonne especially, when the Germans had no matériel superiority, they no longer dominated in any way.

By a close examination of facts, one may convince oneself that the value of the German armistice was due much more to the German war preparations, German matériel organization for war, than to the value of the soldiers and those in command. Had the German been obliged to improve the defence of Argonne as the French were, they would have been defeated at a very early stage.

ARIZONA

In 1920 the pop. was 334,162 as against 204,334 in 1910, an increase of 29,828, or 63 5% . This was the largest percentage of increase shown by any state. The pop. of the chief cities was as follows: Tucson, 20,292 (13,195 in 1910), Douglas, 9,910 (6,437 in 1910), Bisbee, 9,265 (9,019 in 1910). The rural population of the state was 110,570, and the city population was 29,592, as compared with 18,910 in 1910. The rural pop. constituted 64.8% of the whole in 1920 as against 69% in 1910.

Agriculture.—During the decade ending in 1920 agriculture underwent remarkable changes. There was a considerable increase in the number of acres irrigated, from 320,951 ac. in 1909 to 467,349 ac. in 1919, a gain of 46%. Almost a third of this irrigated area was in Yuma county as a result of the Laguna Dam; the greater portion of the remainder was the result of pumping in other counties. The greatest change was the transition from dairy farming to cotton growing. In 1909 there were 18,773 dairy farms in the state, while the dairy business had fallen off extensively. In 1916 the average yield of the Salt River Valley was estimated at 60,000. The introduction of long staple cotton reduced this number to about 8,000 at the end of 1919. As a result of these developments the irrigated land in 1914 there were 13,300 ac. under cultivation, and in 1920, according to estimate, 18,000 ac. This increase, coupled with the great rise in the price of cotton, caused cotton land to rise from $400 and $500 to $700 and in some instances to $1,000 an ac. The great fall in the price of cotton was expected, if it proved permanent, to result in a return to dairy farming and lower land values.

Minerals.—In 1910 Arizona’s production of 297,250,538 lb. of copper placed her first among the producing states. This increased to 599,235,000 lb. in 1920. The tendency during 1910-20 was toward the development of grade deposits, the Miami Copper Co., the Inspiration Copper Co., the New Cornelia Copper Co., and the Ray Consolidated Copper Co. being conspicuous for this type of work. The older companies such as the Copper Queen, the United Verde, and the Calumet and Arizona copper companies still had high-grade deposits in their holdings in the zone of low-grade ores, having completed the stripping of Sacramento Hill near Bisbee. The plant for handling this huge low-grade deposit was to be completed in 1921. The yield of gold and silver was not unimportant. Gold production increased from 153,380 oz. in 1910 to 360,034 oz. in 1920; and silver from 2,666,528 oz. in 1910 to 6,995,251 oz. in 1920. Gold production increased mainly because of the output of the Tom Reid and the United Eastern mining companies, the latter producing one-fourth of the silver in the state in 1920. Considerable amounts of gold and silver were also obtained in treating copper ore.

Manufactures.—The following table shows the growth of manufactures:

<table>

The principal industries in 1920 were the smelting and refining of copper, cars and general shop construction and repairs by steam railway companies, flour-mill and gristmill products, lumber and timber products.

Education.—The progress in public education in the decade 1910-20 was greater than the increase in population. In 1916 a high school of the state was for the first time admitted to the North Central Association of Colleges and Secondary Schools. In 1920 there were in the attendance 44 of 629 high schools of the state, and 60% of the normal schools at Temple and Flagstaff kept pace in enrollment and equipment with the growth of the public schools. In 1919 there had been established a state Teachers College at Miami, and a state Normal School at Tucson: college of Letters, Arts and Sciences; college of Mines and Engineering; college of Agriculture; school of Law and school of Education. The Agricultural Experiment Station, the Arizona bureau of mines, the state pure food laboratory and the state museum were also on the campus. In 1916 the university of Arizona was
admitted to the North Central Association, and in 1919 it became a member of the Association of American Colleges.

History.—During the years 1910-20 Arizona provided two issues of national interest. The first of these was her admission to the Union. As provided by the Enabling Act signed by President Taft June 30, 1910, a constitutional convention met at Phoenix from Oct. 10 to Dec. 9, 1910, to frame a constitution. The constitution then adopted provided that one-fourth of the electors of a judicial district might, by petition, demand the recall of a judge. If he did not then resign a special election could be held to determine whether he should be recalled. In Aug. 1911 the National House of Representatives by a vote of 214 to 57 passed a joint resolution providing for the admission of Arizona on condition that the constitutional provision for recall be submitted to a vote of the people. President Taft had already informed Congress that he would not sign the bill, and, in a message to Congress, took the position that he must veto the measure or assume responsibility for the recall of judges. Later in August he approved a resolution granting statehood on condition that the voters in the general fall election strike out the provision for recall. This they did; and on Feb. 14, 1912 President Taft signed the proclamation admitting Arizona. After the state was admitted the people amended the constitution, inserting the original clause providing for the recall of judges. The presidential vote in 1912 was 10,324 for Wilson, 9,049 for Roosevelt, and 3,021 for Taft; in 1916, 35,170 for Wilson and 20,514 for Hughes; in 1920, 66,086 for Wilson and 43,469 for Harding. The Labour law provided the other issue of national interest. The voters of the State, 1914, by a majority of 10,684, enacted a law providing that when any corporation, company, partnership, or individual employed more than 5 workers, 80% of these should be qualified electors or native born citizens. The ambassadors of Great Britain and Italy claimed that the law violated existing treaties. The U.S. District Court declared the law unconstitutional as conflicting with the Fourteenth Amendment. On appeal the U.S. Supreme Court upheld this decision, Nov. 1, 1915. Justice Hughes in the final decision said that it had already been established that an employer could not pass laws that aroused high party feeling. Governor Hunt, supported by a Democratic assembly, had been elected for two terms. He ran for a third time in 1916. On the face of the returns Campbell, the Republican candidate, was elected; but both candidates came to Phoenix in Jan. to be inaugurated, and Hunt refused to leave the executive office. Later he was compelled to surrender the office to Campbell, but assumed it again in Dec. 1917 after the state Supreme Court had declared him the legally elected governor. At the next election in 1918 Campbell got 92.73% of the vote and was re-elected. The bitter political struggle was largely the outgrowth of an industrial situation that culminated in a number of strikes throughout the state. That at Clifton and Morenci beginning in Sept. 1915 roused the widest interest. This strike, conducted for the most part by Mexican labour, was organized and at first directed by agents of the Western Federation of Miners. The unique characteristic of the struggle was the sympathy for the strikers shown by the chief executive of the state, Governor Hunt having ordered in the early days of the strike that no strike-breaker should be admitted into the district. Another singular characteristic was the absence of the usual violence. This was attributed to the action of the sheriff who deputized strikers themselves to protect the property of the company. There was no loss of life, and although a large concentration plant at Clifton was destroyed by fire, this was not proved to be the work of strikers. After repeated attempts at conference, no settlement was reached till the Western Federation of Miners withdrew, leaving the Arizona State Federation of Labor in charge. An increase of wages was granted; but the managers asserted that this was the natural result of the increased price of copper, and that they had in no way yielded to the strikers. The industrial strike reached even a more crucial stage in the summer of 1917 when the Bisbee deportation incident occurred. The employees in several of the mines had struck for higher wages and better working conditions, claiming that they had been the losers in the general rise in prices, and that they had not shared in the profits due to the increased value of copper. There was a general fear that violence would result from the activities of the Industrial Workers of the World. Sheriff Wheel- er, supported by the conservative citizens of Bisbee, took the position that the members of the I.W.W. and their sympathizers were vagrants, traitors, and disturbers of the peace of the county. In July 1917 the sheriff and his many deputies rounded up over 1,100 of the alleged offenders and deported them to Columbus, N.M. President Wilson at once warned Governor Campbell of the danger of such a precedent; and two months later, at the solicitation of Samuel Gompers, he appointed a committee, of which Secretary Wilson of the Federal Department of Labor was chairman, to investigate and adjust the industrial disputes. This committee found that there was no machinery whereby the grievances could have been adjusted, since the state courts refused to recognize certain labor organisations. The committee further recommended that Congress make future deportations a Federal offence. A number of indictments against Wheeler and his deputies were secured; and one case, the State of Arizona v. H. E. Woolton, came to trial. The defendant was freed on the plea of the "law of necessity"; the other cases were not pressed. The last territorial governor was Richard E. Sloan, 1909-11. State governors were George W. P. Hunt (Dem.), 1911-9; Thomas E. Campbell (Rep.), 1919-25. Mining.—Minerals.—Publications of U.S. Geological Survey and Bureau of the Mint (1920). Recall of Judges: Congressional Record, vol. xlvii., pt. 4, pp. 3964-3966. Cases: Hunt v. Campbell, Pacific Reporter 169; Arizona’s Alien Labor, 219 Federal; and E. S. Bisbee Labor Diplomacy (pub. 1918). Histories: McClintock, Arizona the Youngest State; Board, Contemporary American History. (H. A. H.)

ARKANSAS (see 2,551). In 1920 the pop. was 1,752,204 as against 1,574,440 in 1910, an increase of 177,755, or 11.3%. Of the total pop. in 1920, 1,265,792, or 72.2%, were native whites, 472,230, or 27.2%, negroes, and only 13,075, or .8%, foreign-born whites. There were 211,817 illiterates of whom 79,245 were negroes, 41,411 native whites, and 1,144 foreign-born whites. The pop. was decidedly rural, only 206,497, or less than one-sixth, being classed as urban. The average number of inhabitants per square mile in 1920 was 33.4 as against 30 in 1910. Little Rock was the largest city, with a pop. of 65,142 (45,941 in 1910), of whom 17,477 were negroes. The pop. of the other leading cities was as follows: Fort Smith 28,870 (25,075 in 1910), Pine Bluff 19,280 (15,102 in 1910), and Hot Springs 11,691 (14,434 in 1910). Agriculture.—Agriculture was still the leading industry in 1920 and, in spite of the ravages of the boll-weevil, cotton was the leading crop. In 1916 2,635,000 acres produced 1,134,000 bales, valued at $111,125,000, and 563,000 tons of seed. The crop of 1919 was considerably below, 860,550 bales, valued at $71,157,000. of which 102,000, 1,177,095 bales. Arkansas cotton is of a high quality, the price paid for it being exceeded in America only by that of Florida, California, Arizona and Mississippi. In recent years there has been considerable agitation in favour of diversified farming, and this has caused an increase in the production of cereal crops and hay. The corn crop of 1919 (34,226,935 bushels) was valued at $81,008,482. The production of the rice crop has been very rapid. In 1904 the production was 2,400,000 bushels, in 1910, 6,797,126 in 1919, and 7,780,000 in 1920. The state ranked high in the production of apples, both in quality and quantity. In the production of peaches it ranked next after California, Texas, and Georgia and was said to contain the largest of all orchards. The crop was 3,340,823 bushels in 1919. The strawberry crop was valued at over a million dollars a year. The state ranked fourth in the acreage devoted to vineyards, 71,921 acres being cultivated in 1919, of which 64,872 for the making of wines, the remainder for the production of raisins. In the last few years considerable attention has been given to the introduction of pure-bred live stock. The total value of the farm products in 1910 was estimated at $141,58,356 as compared with $175,037,000 in 1916. Manufactures.—In 1910 there were 2,025 manufacturing establishments employing 44,982 workers and turning out products valued at $110,000,000; of this lumber was the leading industry, cotton-seed oil the second. Sixty different kinds of trees are cut for the market, hardwood and pine being the most common. The annual cut was about 5,000,000,000 board ft., of which 2,011,200,000 was lumber. The supply of standing
timber was estimated in 1920 at 78,700,000,000 feet. The chief centres of manufacturing were Little Rock, Fort Smith, Pine Bluff, North Little Rock, Hot Springs, Fayetteville and Little Rock. Consideration was given to manufactures, especially in glass, in Fort Smith by the discovery of gas.

**Armenia**

There were no special banks or private banks in Armenia. In 1908 and 1914 the state had 76 national banks with capital and reserves amounting to $25,545,357 and resources amounting to $273,915,076. The state banks had 386,383 depositors. There were no national banks, but there were 86 banks, but in 1914 the depositors were amounted to $124,570,100. The increase in the ratio of the banking resources of the state to those of the nation during the years 1909–19 was increased only by Oklahoma and Nevada. There were few bank failures in 1910 and deposits in the small states were supported by a few large state banks.

**Transportation.**—In 1910 the state had 4,876 miles of steam railway; in the same year there were 152 miles of inter-urban lines with 152 miles of track. In the same year 59,058 motor-cars, trucks and tractors were licensed. By the close of 1920 the road-building programme comprised 9,000 miles at an estimated cost of $1,000,000, about one-fifth of which was under construction or contract. Discontent, partly over the cost and partly over the fact that only real estate was assessed to pay for these roads, led to the abandonment of many of those projected. Some of the roads were to be asphalt or concrete, but the prevailing type was gravel. As the counties were forbidden to issue bonds the work was carried on by improvement districts with state and federal aid. The state aid amounted to $15,000,000 in 1917–21 and $20,000,000 in Federal, $4,615,210. To secure this aid, the road work by the districts had to meet the approval of the state highway department.

**History.**—The state continued under control of the Democratic party without interruption from 1874 to 1921. Several attempts have been made to amend the conservative constitution, most of which have ended in failure, owing to the requirement of a majority of the total vote to adopt any amendment. An initiative and referendum amendment was adopted in 1910, but a part of it was declared unworkable by the Supreme Court. In 1916 a new initiative and referendum, submitted by petition, was voted down; in 1920 it received a large majority of the vote cast, but not a majority of the total vote. It was again submitted by petition and will be voted on in 1922. In 1912 an amendment submitted under the initiative limited the pay of legislators to a session of 60 days, with half pay for an extra session of 15 days. The term of the legislature had been long and expensive. The Legislature of 1917 called a constitutional convention. With the advent of a military convention met, the United States had just entered the World War and a strong effort was made to adjourn without doing anything. As a compromise the convention adjourned to July 1918. It then met and submitted a revised edition of the old constitution. This was rejected by the people. Important legislation during the period 1910–20 included abolition of the convict lease system (convicts may now be worked on the roads); provision for a state farm for convicts; reform schools; state-wide prohibition (1913; inheritance tax; minimum wage; restricting child-labour; compulsory education; and abolition of the "fellow servants" rule. In 1917 women were by statute given the right to vote in primary elections; in 1920, before the adoption of the national woman suffrage amendment, an amendment to the state constitution giving full rights of suffrage and the right to hold office was submitted to the voters, but failed to receive a majority of the total vote. A legislative Act of 1921 gave women the right to vote in the state. In 1921 Gov. McCrane induced the Legislature to make a beginning of reform in the state administration by abolishing a number of offices and commissions. The governors of the state since 1900 have been: George W. Donaghey, 1909–13; Joseph T. Robinson, Jan. 8–March 1913; W. K. Oldham (acting), March 8–23; J. M. Futrell (acting), March 23–Aug. 6; G. W. Hayes, Aug. 6 1913–7; C. H. Brough, 1917–23; J. T. McCrane, 1921–

**Armenia** (see 2,626).—The years between 1914 and 1921 are, perhaps, the most important of any in the modern history of the Armenian people. The bloodless Turkish revolution of 1908, followed by the assembling of a representative Parliament, opened a period in which, for a time, racial animosities seemed to have disappeared from the greater part of the Ottoman Empire. Armenians hailed the change as the end of their troubles, and massacre and oppression became dim memories. They appeared content henceforth to be citizens of a reformed Turkey and anxious to bear their part in all the duties of citizenship. Some, indeed, went so far in their new-formed patriotism as to call themselves "Ottoman Armenians," seeking to make a national name of the term hitherto used only by Turkish Moslems—a term embodying in the past the very spirit of Turkish conquest and oppression. Nor was it merely the rank and file of the Armenian people who so readily accepted the prospect of a new Turkey. Leaders of Armenian revolutionary societies—organizations whose purpose was to achieve Armenian independence, the Hunchakists by constitutional means, the Dashnakists by violence—themselves believed that the Young Turk movement deserved well of the Armenian people, and that the revolution should receive Armenian support. We need not enquire too closely into the causes of this sudden confidence. The Young Turks possessed, as yet, little experience in organization; they were deficient in means; they therefore courted leading Armenians and the Armenian secret societies, from which sources, to some extent, experience and financial aid could be obtained. On their part Armenians held that any change which diminished the power of the Sultan 'Abdul Hamid and his creatures was so much to the good; and their leaders felt themselves competent to use the Young Turks for Armenian ends, and to go with them only so far as Armenian interests required. It is, indeed, a singular fact that the Young Turks and the Dashnakists continue to find some degree of usefulness in each other to the present time.

**Cilician Massacres.**—But disillusionment on the part of the Armenian people in general was not long delayed. The first free Ottoman Parliament met on Dec. 27 1908; in April 1909 massacre broke out at Adana, in the rich Cilician plain. After the first outbreak troops of the Young Turk army were hurriedly brought from Salonika, and the affair seemed to have been stamped out by the promptitude of the Government. But after a few days it flared up again, in consequence, it is stated, of Armenians having fired on the soldiery who thereupon took an active part in the work of killing and burning. From Adana massacre spread to various towns of the vilayet of Adana, and even to Constantinople. The Cilician Scholehan and Dataf Mountains, towns of the Cilician plain, and Ker一条龙. Though thousands perished in the towns, a greater number were slaughtered in remote villages and on lonely roads; for it was the time when Armenians from the mountains were on their way to the annual harvesting of the fertile Cilician plain. It is believed that in all not less than 26,000 lost their lives in this unexpected and disastrous outbreak.

**Origins of the Cilician Massacre of 1909.**—The origins of these massacres remain obscure; that some form of official prompting lay behind them, however, cannot be doubted. Not
once but often it has been proved that Turkish authorities find no difficulty in preventing outbreaks of the kind if they choose; that, in fact, massacre is, at bottom, the result of official connivance more or less direct. The Cilician massacres have been charged to 'Abdul Hamid and his satellites, as an effort by them to discredit the government of the Young Turks. They have been charged to the Young Turks, as an effort by them to discredit 'Abdul Hamid, who had been deposed on April 1—just one week before the affair at Adana. Notwithstanding the vehement denial of complicity by the Government, and their ostentatious endeavours to compensate sufferers and provide for orphaned Armenians; notwithstanding the Turkish Commission of Inquiry, and the partial hanging of Moslems and Armenians, time brings the guilt home more and more definitely to Young Turk leaders.

That the Armenians of Cilicia were blameless cannot be maintained. After the first fraternal demonstrations of the revolution they had adopted a manner toward their Moslem fellow citizens provocative and unwise beyond belief. They had indulged in Armenian national processions, displaying the flag of an independent Armenia; had publicly boasted that Cilicia itself was soon to become an independent Armenia; had insulted and beaten Moslems in the streets of Adana. To the fatal influence of these follies were added the economic facts that Armenian land-owners, already in possession of the richest areas of the Cilician plain, were rapidly increasing their holdings; and that the Armenian population prospered and multiplied while the Moslem population declined. The Moslems of Cilicia, indeed, were gloomily brooding over Armenian affronts to their patriotism, and economic Armenian encroachments on their position as the dominant and ruling race. These matters combined formed a mass of highly inflammable material.

Armenian Political Position.—As the Young Turk Government consolidated itself, and its control passed finally into the hands of the Subtanneen Committee of Union and Progress, so the prospect of Armenians receiving equal treatment within the Empire disappeared. Armenian representation in Parliament was curtailed by means both direct and indirect. The total number of Armenians who might sit in the Chamber was arbitrarily fixed, irrespective of election results. The lists of voters were compiled under conditions that weighed against Armenia. Many who voted in favor of Armenian amendments were not accorded even the names that entitled them. In common with other Ottoman Christians the place of Armenians in the State became, in effect, that of undesirable aliens.

Turkish Wars of 1911-3.—The Italo-Turkish War of 1911-2 passed without changing the Armenian position. Nor did the first Balkan War, 1912-3, greatly affect the race except as to military service. During these wars it seemed, indeed, that massacre did not suit the policy of the Government, the desire being to stand well with the Powers. None therefore took place. In the Balkan War, however, military service fell heavily upon the Armenian subjects of the Empire for the first time. They were not permitted to serve forming Armenian units, but were distributed throughout the army; and the most laborious and dangerous duties are said to have been assigned them as a matter of policy. In these circumstances desertions were numerous, as might have been expected. But with none of the incentives usually prompting the soldier to high performance, with everything, indeed, against them, the Armenian elements, as a whole, earned the commendation of Nazim Pasha, the Turkish commander-in-chief, who declared in one of his despatches that the Armenian soldiers had performed their duty loyally and with courage.

Attempts by the Powers to ameliorate the political situation of the Armenian people were continued after the close of the Balkan War. Agreement with the Turkish Government seemed promising at the beginning of 1914, on the basis of an increased number of Armenian deputies for the Ottoman Parliament, and for the supervision of Ottoman officials in the "Six Villayets" of Eastern Turkey-in-Asia by two European inspectors general to be selected by the Powers. There was also to be equal representation of Moslems and Christians on the councils of the vilayets of Van and Bitlis, in which districts the Armenian population was presumed to equal the Moslem. But the proposed reforms came to nothing. The Young Turk Government already had prevision of great events to come, and were temporizing in anticipation of developments.

The World War.—Between Oct. 29 and Nov. 5 1914, the action of the Young Turk Government resulted in war being declared on Turkey by Great Britain, Russia, France and Serbia. In committing their country to support of the German Powers the Young Turk leaders saw, as they thought, the great occasion for recovering lost Turkish provinces and reestablishing the Ottoman Empire on the widest foundations, with corresponding advantage to themselves. They believed that with Germanic support they were speculating in certainties. They resolved to use the fortunate opportunity thus presenting itself for making an end of Ottoman internal difficulties as they saw them. Chief among these was the question of the Christian people, of Asia Minor, the Ottoman Greeks and the Armenians, who cherished national aspirations incompatible with Ottoman sovereignty. The "Turkification" of the whole population of Asia Minor—the creation of a single homogeneous race for this great area—was the underlying purpose.

Policy of Massacre and Deposition.—How the policy for dealing with the Armenian part of the question took form we do not know. Probably Talat Pasha and Enver Pasha had as much to do with it as any—Talat at least is credited with its application—but they only sought to follow, on a greater scale, the example set in past years by 'Abdul Hamid. A preposterous and cynical scheme of compulsory colonization as part of the policy has been attributed to German theorists; but it was not even a mask for an existing policy of the young Turks. The creation of a single homogeneous race for Asia Minor was the purpose.

The Armenian race was to be uprooted from the wide territories of Asia Minor beyond hope of continuance or return. From convenient areas those of the people able to march were to be deported to Mesopotamia and eastern Syria. Being an industrious and prolific race they might, in Mesopotamia, at least, do something toward creating a profitable, taxpaying province in place of one requiring incessant Ottoman outlay. Armenians from provinces too distant for deportation to be practicable were to be exterminated or driven to a fugitive existence.

Statistics of Armenian Population.—The following figures show the numbers and distribution of the Armenian race in Trans-Caucasus and Asia Minor, the destruction of which, or at least of the portion contained in Ottoman territory, was to be accomplished. In Russia Armenian figures are those of the Russian census of 1916. For the Turkish vilayets they are, in the absence of any authoritative and reliable statistics, an exhaustive and impartial estimate for the period immediately before the war:

The Policy in Execution.—It is unnecessary to follow in detail the execution of the infamous policy for the destruction of the Armenian population of Asia Minor. Suffice it to say it was begun soon after the outbreak of war by concocting reports of Armenian revolutionary plots in support of the Allied Powers; and then, as far as possible, by a general disarmament of Ottoman Armenians. Though British operations in Gallipoli and Mesopotamia, and Russian operations against the eastern vilayets, kept the Turks occupied in a military sense, they did not prevent Turkish activity against Armenians. During the spring and summer of 1915, indeed, when the fate of Constantinople and Turkey hung in the balance and inhabitants of the Imperial City daily scanned the Sea of Marmora for signs of an approaching British fleet, the Young Turk Government prosecuted their Armenian policy with the utmost rigour. But when the Gallipoli operations had plainly failed, and the outcome of the war was thought to be no longer in doubt, a Turkish defeat in Russian Armenia, attributed by Enver Pasha to the Armenians, was revenged upon the race by massacres of even greater ferocity. From first to last they were organized and carried out systematically. Massacres on the largest scale took place at Bitlis, Sivas, and Van, but wherever, in fact, a considerable and more or less defenceless Armenian population existed. The people were butchered in masses, butchered in groups, drowned in the Black Sea and in rivers, burnt in buildings—killed by whatever processes were found most ready and convenient. Girls were placed in Turkish harems. It should not be supposed, however, that no resistance was offered, that the Armenian people sold their lives cheaply. Although supposed to have been disarmed, weapons remained, and on numberless occasions, in untold villages and towns, a hopeless resistance inflicted severe losses on the attackers.

Deportation, too, became an easy indirect means of destroying Armenian life. On the long routes of eastern Asia Minor by which movement took place; on the subsidiary roads leading to these routes; at the great concentration centres on which the columns of suffering humanity were directed, the Armenian people died of hunger, exhaustion, exposure, disease, in tens of thousands, perhaps in hundreds of thousands. Only a comparatively small proportion of those who set out reached the destination assigned them. The policy of transferring an Armenian population to Mesopotamia and Syria became in execution a wholesale means for destroying those who were despatched.

Estimated Loss of Armenian Life.—The Armenian policy of the Young Turks failed, however, in that part of Turkey-in-Asia lying between Erzerum and Bitlis and the Russian frontier. In this region, where the Armenian inhabitants were comparatively numerous, they were able to pass into Trans-Caucasia, or were preserved by the advance of the Russian armies. Within the stricken areas of Asia Minor, too, many escaped—many more than are generally supposed. Kurdish tribes gave friendly shelter; even Turks were not without compassion; the nature of the country, itself, afforded opportunities for escape and concealment. A large number, and in the Anti-Taurus mountains were Armenian fastnesses unrequited by Turkish forces.

Armenian estimates of the losses suffered by their people as the result of the Young Turk measures are liable to be excessive. It is in the nature of things that they should be. But if we place the loss of life directly and indirectly caused by massacre and deportation since the year 1914 as being in the neighbourhood of three-quarters of a million we cannot be very far from the truth. In addition are what may be called the legitimate losses of war, and these, in proportion to the manhood of the Armenian race, were enormous.

As regards the Armenian population, not only of Asia Minor, but of Trans-Caucasia as well, from first to last Russia is believed to have sent 160,000 Armenian troops from Trans-Caucasia to her battle-fronts in Europe, of whom less than 30,000 survived. For operations in Asia Minor she subsequently raised an Armenian volunteer army, and swept into it refugees from Turkish territory. From 1914 to 1921 Armenians were fighting incessantly in Asia—for Russia; for the French in Cilicia and Syria, where many thousands were embodied; and for themselves in Trans-Caucasia. Probably not less than one-sixth of the males of the whole race perished in warfare, in addition to loss by massacre and deportation.

Russian Policy.—A brief outline must now be given of the military operations of Tsarist Russia against the Ottoman Empire during 1914-6, for they deeply affected Armenia and the Armenians. For more than two centuries it had been the traditional policy of Russia to obtain possession of Constantinople and the other provinces between the Black Sea and the Mediterranean. In the last 40 years she had seen her line of approach through the Balkan Peninsula made impracticable. Correspondingly her line of approach from Trans-Caucasia had gained immensely in importance. She had further established her naval supremacy in the Black Sea over any Turkish force that could be concentrated in those waters. With this as her policy, and in these circumstances, Russia, both openly and covertly, opposed all measures encouraging the development of Armenian national sentiment and aspirations, not only among the Armenian population under her rule in Trans-Caucasia, but also in Turkish Armenia. Turkey, in fact, desired Armenians in Turkey to remain a docile and disintegrating element in the Ottoman Empire, particularly in the eastern vilayets, until such time as she should be able to make further annexations. An independent Armenia, it thus appears, was impracticable during the existence of Tsarist Russia.

When war broke out between the Allied Powers and Turkey Russia recognized that the supreme opportunity for achieving her dearest ambition had arrived. Following the decision of the British and French Governments to send a military expedition to the Dardanelles, she made a formal request to her Allies that her claim to possession of Constantinople and the Straits at the conclusion of the war should be admitted in advance. A week later the Western Powers agreed to the proposal, and the destiny of the greatest strategical position in the world, and with it the destiny of Armenia, seemed to be definitely settled.

Russian Invasion of Turkish Armenia, 1914.—Russian troops crossed the frontiers on Nov. 4, 1914, two days after the declaration of war, and advanced towards the great Turkish fortress of Erzerum. But the movement had no weight; it ceased after a few weeks of indecisive fighting, and the Turks launched a daring counter-offensive against Ardahan and Kars, in Russian Armenia. This reckless movement was ended, however, at the battle of Sarikamish (Dec. 29, 1914 to Jan. 1, 1915) at which, and at the battle of Kara Urgan in the subsequent retreat, the Turkish army was almost destroyed. In revenge for the disaster, attributed by Enver Pasha and the Young Turks to Armenian elements in the Russian army, and to support and intelligence given by Armenians generally, exterminatory measures against the Armenian population of Asia Minor were redoubled at the beginning of April, 1915. It was at this stage that the British and French Governments issued (May 24, 1915) a declaration that they would hold Ottoman ministers personally responsible for the massacres.

Armenian Troops in the Russian Armies.—Here it may be remarked that when Russia mobilized in Aug., 1914 for the World War, her Armenian troops, numbering, it is said, more than 120,000 men, were despatched to European fronts. When war with Turkey demanded great armies in Trans-Caucasia these troops were not available. But as a matter of policy Russia raised an auxiliary volunteer army of Armenians, including many thousands of refugees from Asia Minor, for service against the mortal enemy of their race. To these and other Armenians in the Russian armies of Trans-Caucasia—natives of the region, inured to its climatic conditions, between whom familiar with every road and mountain path, and animated by every incentive to fierce and resolute combat—must be credited no small measure of the success which attended Russian arms against the Turks. Not without cause did Turkish leaders attribute their Caucasian disasters to their Armenian enemies.
Capture of Erzerum.—Stagnation followed on the Erzerum front for more than a year after the battle of Sarikamish. But during the spring and summer of 1915 a Russian army, operating in the neighbourhood of Lake Van, invaded and occupied the greater part of the Turkish vilayets of Van and Bitlis, peopled largely by Armenians. This southern campaign, however, had no serious importance except to distract Turkish attention and save an Armenian population. The one line of military advance from Trans-Caucasia into Anatolia lay through Erzerum; and Russia was preparing for an unexpected spring upon this eastern bulwark of Anatolia. A great Russian army, including Siberian and Armenian troops, was concentrated within striking distance of the Erzerum position in the middle of winter. It advanced on Jan. 11, 1916, and two weeks later had reached the outposts of the fortress, a march of some 80 m., with guns and supplies, through deep snow, at high altitudes, in temperatures often below zero. On Feb. 16-17 various commanding mountain forts, the main defences of Erzerum, some of them 9,000 ft. above sea-level, were taken by storm. The city was captured on Feb. 16—its last a resounding disaster for the Ottoman Empire.

Invasion of Anatolia.—When the spring of 1916 came the Russians continued their operations westward, and by the end of July they had captured the Black Sea port of Trebizond and the important military position of Erzincan. They had reached a line about 30 m. west of Erzinjan, stretching from the Black Sea to the Euphrates and thence eastward to Lake Van and the Persian frontier, a line embracing the chief areas of Armenian population in Asia Minor. The line so held was nearly the same as that subsequently awarded by President Wilson as the western and southern frontiers of Armenia.

The Russian Collapse.—But this was Russia’s farthest. She was weakening at home, where symptoms of upheaval were already appearing. On March 14, 1917, a Provisional Government was proclaimed; the Tsar abdicated the following day; in September Russia was a republic, and on Nov. 17 Lenin and Trotsky seized the reins of power. The Treaty of Brest Litovsk, in which Germany imposed terms on her beaten and exhausted enemy, was signed on March 3, 1918. The armed forces of Russia engaged in the war in western Asia lost their fighting value in 1917. The fleet at Sevastopol mutinied in June of that year and removed its officers; and the armies in Asia Minor were in process of disintegration at the same time. When the treaty of Brest Litovsk was signed these armies were only held together by the great personal influence of the Grand Duke Nicholas, viceroy and commander-in-chief in Caucasia, but had already voluntarily retired behind the Russo-Turkish frontier of 1914.

Treaty of Brest Litovsk.—In the Treaty of Brest Litovsk Turkish claims were not overlooked, in fact the treaty gave fulfilment to some of the wider ambitions which had developed in the Young Turk party. It provided, in effect, that between Russia and Turkey the frontiers should be those existing prior to the Russo-Turkish War of 1877-8; under this provision, therefore, the old provinces of Ardahan, Kars and Batum were to be returned to Turkey. Of these, Ardahan and Kars formed part of Russian Armenia, or Erivan.

Even prior to the signing of the Treaty of Brest Litovsk Turkey had been able to take advantage of the growing weakness of Russia. As early as Aug. 1916 she had recaptured the towns of Mush and Bitlis. But immediately after the signature of the Treaty she pushed her troops forward and between March 12 and April 27 recaptured in rapid succession Erzerum, Sarikamish, Van, Batum and Kars. The liberation of Turkish Armenia by Russia had failed, and the disaster involved the return to Turkish rule of a large part of Russian Armenia. The only hope for the Armenian people now lay in themselves—in whatever of wise prevision, unity and sacrifice they could command.

Federal Republic of Trans-Caucasia.—Steps in the right direction had, indeed, already been taken. The approaching collapse of Russia became apparent to Trans-Caucasian people early in 1917. On Sept. 20, 1917 a Council of the Trans-Caucasian Peoples—of Armenia, Azerbaijan and Georgia—assembled at Tiflis, proclaimed Trans-Caucasia a Federal Republic, and formed a Provisional Government. When Turkey, after the Treaty of Brest Litovsk, proceeded to overrun western Trans-Caucasia this Government attempted to negotiate a peace but found the endeavour fruitless. Not only were the Turkish leaders obdurate but the republic had no real unity among its parts. Both Georgia and Azerbaijan, with a Moslem population, though desirous enough of maintaining its independence, saw no great danger in Turkey recovering lost provinces at the expense of the Christian Armenians of Erivan; Erivan feared veiled annexation by Georgia under the guise of federation; and all three peoples were widely at variance upon questions of territory to which each thought itself entitled.

On April 13, 1918 the Federal Republic broke off relations with Turkey and declared war. Two days later the Turks occupied Batum, and on April 22 the Council of the Republic decided to proclaim its independence, but also to resume negotiations with Turkey toward peace. With such wavering of policy the republic was likely to be short-lived.

The end came even sooner than was expected. On May 26, 1918 the three states of the republic fell apart, each declaring its independence as a separate republic, and organizing a national Government of its own.

Armenian Republic of Erivan.—We now reach the point where the story of Armenia, hitherto the story of a dispersed people without a country, crystallizes into a story of an independent Armenian state—a state born to misfortune and bloodshed, surrounded by enemies, and inaccessible to its friends, a state whose survival and growth are matters more for hope than for confidence.

The territory of the republic of Erivan, excluding the districts in dispute with the adjoining republics of Georgia and Azerbaijan, comprised the two Russian provinces of Erivan and Kars, possessing an area of some 17,000 sq. miles. By the census of 1916 these provinces contained, in round figures, a population of 1,510,000 of whom 705,000 were Armenians, 575,000 Moslems, and 140,000 of various other races. But the effective territory and population of the Erivan Republic were even less at the time of its independence. It was declared, for nearly one-third of its whole area was in Turkish occupation under the terms of the Treaty of Brest Litovsk. De facto recognition, however, was accorded the republic by the Allied Powers.

Outside the confines of the state so indicated lay other territories claimed by it, but claimed also by Georgia or Azerbaijan. Rather more than 2,000 sq. m. were thus in dispute with Georgia, and some 12,000 with Azerbaijan. The census of 1916 gave the disputed areas a population of about 900,000 equally divided between Armenians and Moslems. Part of the area claimed both by Erivan and Azerbaijan were the mountainous districts of Zangezur and Karabagh, peopled by Armenian highlanders, perhaps the finest representatives of their race. These, however, were separated from Erivan by an area in which a Moslem population predominated.

At best the territory occupied by the republic was an unfruitful region of treeless mountains and valleys containing little cultivated land, few resources, and a people reduced to the edge of poverty. Even in time of peace it had raised barely sufficient food for the needs of its thirsty population, but now when 450,000 refugees had poured into it, chiefly from Turkish Armenia, the question of supplies became more and more acute. The existence of the republic, indeed, was threatened by the difficulty of obtaining supplies, not only of food but of munitions and fuel.

But the republic was faced with many other difficulties, some external, others internal; the greater number immeasurably intensified by the country’s unfortunate geographical position. Erivan was, in fact, an Asiatic Switzerland, though far more remote from the sea and more inaccessible. The only line of railway communication towards the western world ran through Georgian territory to the Black Sea port of Batum, the only roadway to the sea was also through Georgia to Batum. And
Batum at this time was in the hands of the Turks, and the Allies were still shut out from the Black Sea.

External difficulties were the active and veiled hostility of neighbouring states. Between Erivan and Turkey was the task the avowed purpose of the Allies to free the subject races from the desperation of a life-and-death struggle. Between Erivan and Aserbaidschan was the standing enmity of Armenian and Moslem, given definite point by the massacre of Armenians at Baku some 15 years earlier, and of Moslems by Armenians during the months following the declaration of Armenian independence. There was also the acute question of territory in dispute, accompanied by incessant border fighting. Between Erivan and Georgia trouble, at the moment, was chiefly upon opposing territorial claims. Another hostile external influence was, a little later, exerted by Gen. Denikin and his supporters, who aimed at destroying the independence of the Caucasian republics and reuniting them to a resurrected Russia.

Internal difficulties, apart from poverty and questions of the supply of food, clothing, munitions and medical stores, were caused, also, by the absence of administrative experience among Armenian leaders and the sinister influence wielded by the Dashnakists. This Armenian secret revolutionary society held an extreme socialism; it was thus to a large extent in sympathy with the Bolsheviks of Russia. At the same time it stood for an aggressive military policy by the Erivan Republic and the extension of territory at the expense of adjoining states.

British Expedition to Baku.—Operations which might have had far-reaching results for Erivan and other Caucasian states led to the occupation of Baku in the republic of Aserbaidschan, on July 28, 1918, by a small British force. It had come from Mesopotamia through Persia, and thence up the Caspian Sea—a hazardous expedition intended to prevent, if possible, the despatch of German or Turkish detachments from Caucasus into Central Asia, and to open communications with the Caucasian republics. It had relied upon receiving local Armenian support but this hope failed owing to the extreme weariness of the Armenian population. The Turkish troops which had already entered Aserbaidschan received reinforcements early in September, and then attacked the town and compelled the British force to reembark on Sept. 15.

Armistice of Mudros.—The Armistice of Mudros, signed on Oct. 30, 1918, ended hostilities between the Allied Powers and Turkey. Better days seemed now to be in sight for the Armenian race. Turkey was crushed, the Young Turk Government had fallen into disrepute, the chief leaders were in flight, and it was an aggressive military policy by the Erivan Republic and the extension of territory at the expense of adjoining states. The Armistice contained conditions that specifically relieved the position for Armenians. The Straits were opened, Allied warships reached Caucasian ports and Allied and American relief work was begun. Trans-Caucasia was to be evacuated by Turkish troops, an Allied garrison placed in Batum and elsewhere if necessary, and Armenian prisoners-of-war and interned Armenians released forthwith. Another clause provided for Allied occupation, in whole or part, of the six Armenian vilayets of Asia Minor in case of disturbances arising.

Report between Georgia and Erivan, 1919.—The collapse of Germany and the Armistice of Nov. 11, 1918, marking the complete victory of the Western Powers, seemed to promise the eventual creation of an Armenian state containing a majority of the race. But with Turkish occupation ended the Caucasian republics fell out more seriously among themselves. In spite of Allied efforts to prevent hostilities war broke out between Georgia and Erivan in Jan. 1919; fighting also continued between the Armenians of Karnabagh and Moslems of Aserbaidschan. At this time, too, the intrigues attending Gen. Denikin's movement went far to embroiling the republics. These unfortunate struggles did not, however, last long, nor were military operations undertaken on a serious scale, but the old causes of enmity remained, increased now between Georgia and Erivan by disputes regarding use of the Batum-Erivan railway, and the customs dues levied by Georgia on goods for Erivan.

Paris Peace Conference.—On Jan. 19, 1919 the Peace Conference at Paris began its deliberations, from which, when Eastern problems could be reached, it was hoped that a satisfactory settlement of Armenian affairs might emerge. Each of the Allied delegations had to lay its claims before the Conference. Meanwhile the Supreme Council, acting as an executive body, despatched an Allied High Commissioner to Erivan to compose, if possible, the urgent differences between the rival republics.

Armenians of Erivan had agreed to join Armenians of Turkey in seeking the creation of a single Armenian state; the Armenian delegation at Paris therefore represented the whole Armenian race. The claim advanced by the delegation was, in brief, that to Erivan should be added the eastern districts of Asia Minor in which a considerable Armenian population had existed prior to 1914, and that these districts should include Cilicia as being the "Lesser Armenia" of medieaval history.

But this comparatively moderate proposal bristled with difficulties, and traversed principles to which the Conference professed adherence. Ancient and medieaval history offered feebler arguments for the recovery of territory from a race which could show effective occupation for the past 400 years. Nor did any juggling with ethnological figures assist the Armenian case, for the plain fact remained that in no vilayet of Asia Minor, even before the massacres and deportations, was there an Armenian majority over Moslems. The principle of self-determination by inhabitants would therefore, if applied, destroy Armenian claims.

The Armenian case stands, indeed, on firmer ground than doubtful historical sanctions and self-determination by a mosaic of local populations. Based on justice and high experience it becomes a cause which no amount of theory can set aside.

Stated plainly the case for Armenia put forward by the delegation was that by race, language, faith, old history, servitude and suffering, Armenians were the legitimate heirs of the European side of the Ottoman Empire from Turkish rule. The Armistice contained conditions that specifically relieved the position for Armenians. The Straits were opened, Allied warships reached Caucasian ports and Allied and American relief work was begun. Trans-Caucasia was to be evacuated by Turkish troops, an Allied garrison placed in Batum and elsewhere if necessary, and Armenian prisoners-of-war and interned Armenians released forthwith. Another clause provided for Allied occupation, in whole or part, of the six Armenian vilayets of Asia Minor in case of disturbances arising.

In 1919, and the earlier half of 1920 the prospect of finding a Power who would undertake the onerous and costly task of mandatory grew less and less favourable. It had been hoped that America would accept the responsibility. The American people had shown much sympathy with the Armenian cause; politically America was disinterested and stood outside the jealousies of European powers; her prestige was great; her resources unimpaired; to the Armenian people she would have been their first choice as mandatory power. But the American Senate rejected the offer, fearing entanglement in Old World affairs. Great Britain, France, Italy, each felt unable to undertake the position—war had left them more or less exhausted; and their peoples would not incur the certainty of additional outlay of blood and resources. The Supreme Council
proposed that Armenia should be placed under the League of
Nations; the League decided that the acceptance of mandates
did not fall within its purpose. And when, at a later date, Armenia
applied for admission to the League membership was refused
her.

The Treaty of Sèvres and Armenia.—The Treaty of Sèvres, imposed
upon Turkey and signed on Aug. 20, 1920, provided for the cre-
ation of an enlarged Armenian state and for the settlement of
its boundaries. In Caucasia they were to be adjusted by
direct agreement between the states concerned or, in failure of
that method, by the Allied Powers. In Turkey they were to be
defined by President Wilson as arbitrator; and the Treaty
bound Turkey to accept his decision, but limited the area
subject to the treaty to the whole or parts of the vilayets of Trebizond,
Erzerum, Van and Bitlis. The interests of Armenians remaining
in Turkish territory were safeguarded under the Protection of
Minorities clauses of the Treaty.

President Wilson's Award.—The award defining the Turkish
frontiers of Armenia was given by President Wilson in March
1921. It assigned to Armenia the greater part of the vilayets
of Trebizond and Erzerum, and the whole of the vilayets of
Bitlis and Van—in all an area of about 30,000 sq. miles. The
award gave the territory essential to the creation and develop-
ment of a self-supporting state. It included the greater part of
the eastern districts of Asia Minor containing the bulk of
the Armenian population in Turkey. It provided a coastline for
the state of about 150 m., and included the historic seaport of
Trebizond on which north-eastern Asia Minor depends for
access to the sea. And while fulfilling these conditions it brought
within Armenian territory as small a proportion of Turkish
Moslems as might be.

Wrecking of the Award.—But however admirable in itself,
President Wilson's decision took Armenia little further towards
actual possession of the territory awarded under the terms of
the Treaty of Sèvres. The Peace Conference might assign the
territory by treaty; the Turkish Government at Constantinople
might accept and sign the treaty; and President Wilson might
define the boundaries; but for Armenia to gain possession was
another matter. It was on this difficulty—a difficulty to be
overcome only by use of a great military force—that the fair
prospect of an enlarged and independent Armenia was wrecked.

Even before the acceptance of the Treaty of Sèvres by the
Constantinople Government the Turkish Nationalist movement
had appeared in Asia Minor. Its chief purpose was to offer
armed resistance to the execution of any treaty involving the
transfer of Ottoman territory to Greece and Armenia. Whether
the movement originated with the discredited Young Turk
leaders or was a genuine movement recognized by them as
a promising means to their own restoration to power, is not clear.
But the movement grew rapidly in strength. Within a year the
Nationalist Government, organized at Angora, was sovereign
not only in Asia Minor, but had overshadowed the Constantinople
Government and become the real rulers of the whole of Turkey.
And as the movement gained in strength so the old Young Turk
leaders reappeared—Ta'at Pasha, Enver Pasha, Kemal Pasha,
and others—promoting an alliance with Bolshevik Russia;
urging Pan-Islamic ambitions, and apparently forming with
their followers the extremist Left wing of the Nationalist move-
ment. To suppress this rival Government, even had there been
no secret concord between the two, was beyond the power of the
Government at Constantinople. Nor were the Allied Powers in
a position to enforce a treaty by a great new war involving
expense. Still less was any single Power willing to undertake
the task. Beaten and dismembered though the Ottoman
Empire was, there still remained in Anatolia a reserve of strength,
which, in combination with the great military difficulties
presented by the country, and aided by Bolshevik Russia, was
able to defy and thwart the decisions of the Peace Conference.

Greece, indeed, her own territorial gains at stake, and sup-
sported by the Allies, commenced military operations against
the Nationalists in May 1920; and it seemed probable that the
Armenian cause might benefit. The republic of Erivan there-
fore prepared to send troops into the territory assigned her by
the Treaty of Sèvres, and desultory fighting occurred. Turkish
strength in eastern Asia Minor, however, was too great for the
small force Erivan could spare from other fronts to have any
prospect of success, and no actual invasion of Turkish territory
took place. Meanwhile Greek armies encountered little resist-
ance and occupied a large area of western Asia Minor. These
operations, however, in no way crushed the Nationalist power.

In Feb. 1921, Greece undertook yet greater operations; this
time unsupported by the Allies, and in defiance of their wishes.
She aimed at destroying the Nationalist forces and capturing
Angora; but by the end of March her armies were driven back,
and she found that an offensive on a vastly greater scale would
be necessary to ensure success. To this yet more serious cam-
paign she definitely committed herself in the summer of 1921.

The Bolsheviks in Caucasia.—To complete this historical
sketch, it is only necessary to glance more particularly at the
unhappy events in Caucasia and south-eastern Asia Minor
during 1920-1, for in this period the tragedy of the Armenian
race seemed to have reached its climax.

The Bolshevik occupation of Baku, at the close of April 1920,
ended the independence of the republic of Azerbaijan and
established a Soviet Government in alliance with Moscow; it
also brought Bolshevik forces into an area whence they could
apply pressure to Georgia and Erivan. Bolshevik Russia and
Nationalist Turkey were even now working together. Apart
from strictly Bolshevik aims the common purpose existed of
establishing direct communication between Russia, via Baku,
and Nationalist Turkey. This could only be done through
Erivan and Georgia by railway, or through Erivan by road;
the republic of Erivan, in fact, completely barred both routes.
In spite of Bolshevik propaganda in Erivan the people as a
whole were strongly opposed to Bolshevism, and when in May
Bolshevik forces in Azerbaijan attacked Erivan they encoun-
tered a vigorous defence, and were repulsed. Moscow now endeavoured
to negotiate a treaty of alliance with Erivan, but the terms
offered were too severe. They included:—the right of transit
through Erivan by rail for Soviet troops; the cession of
the disputed districts of Karabagh, Zangezur and Nakhichevan
to Bolshevik Azerbaijan; and the control of the foreign policy of
Erivan by the Moscow Soviet. Erivan refused, but in July it was
served with an ultimatum requiring it to evacuate the three
districts just named.

The isolated republic had been in desperate straits for food,
fuel for its railways, munitions and clothing for its troops; but
supplies of munitions and uniforms, sent from England, reached
the country just before the ultimatum was presented. For
allowing the passage of these vital supplies through Georgia that
republic, however, had insisted on retaining 20% of everything
by way of toll.

While Soviet Russia applied pressure upon Erivan from the
east, Nationalist Turkey did likewise from the west. The
outcome was that the republic agreed to the occupation of
Karabagh, Zangezur and Nakhichevan by Bolshevik troops, thus
giving direct road communication between Azerbaijan and
Nationalist Turkey. With the very existence of Erivan thus
threatened and conscious that the same danger hung over their
own country the Georgian people might have been expected
to make common cause with their Armenian neighbours. The
danger, however, seemed to them less; they had open commu-
nication by sea and could, they thought, await developments.
They preferred to keep Erivan's troops on their borders; but gave no active assistance
to Erivan.

The Full Republic of Erivan.—By Sept. everything was in readi-
ness for the next act in the tragedy. At the end of the month
a Turkish Nationalist army suddenly attacked and captured
Olti on the western frontier of Erivan. In the meantime
Bolshevik forces in Azerbaijan were massed along the railway
skirting the northern frontier of the unfortunate Armenian
Republic. An overwhelming Turkish advance was then made
along the railway upon the great fortress of Kars in the heart of
Erivan. Armenian troops checked the advance for a time, and
compelled a Turkish retreat, but it was only a temporary set-back; Kars fell, and the advancing Nationalists captured Alexandropol in November. Bolshevik risings broke out in the capital and other towns; the resistance of the republic collapsed, and the city of Erivan was speedily occupied by Turkish troops. At this stage a Soviet Government was set up, and the republic of Erivan became, in name, a Soviet Republic in alliance with Moscow. But even so it was a republic much reduced in area. In agreement with Moscow Turkey took possession once again of the districts of Kars and Ardahan, from which the Allied Powers had ejected her in Nov. 1918; and to this territory was added enough to bring the railway from Azerbaijan to Erzerum within Turkish possession. Only in the region of Karabagh was any vestige of Armenian independence preserved; there, indeed, the Armenian mountaineers repudiated Soviet Government and, so far, seem to have retained a precarious but independent existence.

With Turkish forces in occupation of Erivan, a state which had driven to form a Great Armenia by the acquisition of Turkish territory, massacre might have been foretold. It was hoped, however, that the Turkish influence would turn out to be bloodshed, but the hope had no real ground for existence. At Olti, Kars, Alexandropol, and then in the city of Erivan, massacres on a scale comparable only with those of 1915-6 took place; and if this policy was followed in the towns it was followed in the villages as well. The total loss of life cannot be estimated, but was certainly great. When the snow melted in the spring of 1921 thousands of Armenian corpses were revealed, heaped together, just as they had fallen in the closing months of 1920.

**Cilicia and S. Asia Minor.**—In Feb. 1920 Turkish Nationalist forces began serious operations against Cilicia, then in occupation by French troops as part of the French sphere of influence. They defeated various French detachments, captured the large town of Marash, and there, and elsewhere in Cilicia as opportunity offered, resumed a systematic massacre of the Armenian population. The position was the more disastrous because, relying upon French protection for the future, a great immigration of Armenians into Cilicia had taken place; it was credibly reported, indeed, that some 20,000 of the race perished in south-eastern Asia Minor during the spring of 1920. At this stage the Allied Powers, who had recently decided that Constantinople should remain in Turkish hands, were reluctant to reconsider their decision unless effective Turkish protection were given to non-Muslim elements of the population in Asia Minor. The warning seemed to have some effect at the time, though later developments diminished its influence.

A definite Nationalist policy lay in the Cilician operations, however haphazard and casual they may appear. The idea had been broached, chiefly among Armenians, of creating a Franco-Armenian State in south-eastern Asia Minor—of, in fact, reviving the Lesser Armenia of history, and placing it under French protection. The hope that this scheme would mature was one of the influences which brought a large Armenian population into Cilicia in 1916. Nationalist operations in this region were designed to thrust the project by exterminating the Armenians, and involving the French in irritating and costly hostilities in defence of the territory. Warfare on a small scale continued during the greater part of 1920; for not only had the French their hands full in Syria, but they were anxious to avoid pushing matters to extremes with the Nationalists. They hoped, in fact, for an arrangement.

**Siege of Hajin.**—One of the most unhappy affairs of the Cilician War was the siege and capture of Hajin by the Nationalists. The town, a remote and isolated stronghold among the Anti-Taurus mountains, was held by its inhabitants against all Turkish attacks until Oct. 1920. Ammunition, however, ran out; expected relief never came; and in the end the town was stormed, and the greater portion of the population, numbering several thousands, perished in the usual massacre.

**French Negotiations with Nationalists.**—At the beginning of 1921 the French and the Nationalists came to an agreement by which, in return for important economic concessions in wide areas of Asia Minor, France was to vacate Cilicia. The National Assembly at Angora refused to ratify the agreement, on the grounds that it surrendered too much and obtained too little. They desired, in fact, possession of the port of Alexandretta which the French had retained. Negotiations, however, were continued. The hope that a Franco-Armenian State might be established in Cilicia had small prospect of realization unless a change should take place in French policy in these regions.

**ARMOUR, F. S. V.**—**ARMOUR CARS**—The armoured car was a mechanically propelled vehicle equipped with protective armour and adapted as a fighting machine. Its first form consisted of a motor chassis with iron plating and sides fitted with loopholes for the crew to fire from. It rapidly developed into a miniature armoured fort on wheels with machine-guns and searchlights mounted in the most effective manner. This first type was liable to be put out of action by bombs thrown over the iron plating or from the windows of houses, and the iron plating was not proof against modern high-velocity rifle fire. The next improvement, therefore, was to place armour over the top. It was soon found that the requirements in the armament and arrangement of armoured cars were similar to the practice in the navy, and that, provided a car could be kept mobile, the next main essentials were good range of observation and an all-round field of fire. This soon produced the turret cars, with a single revolving turret and one Vickers machine-gun; and subsequently a type of car with two turrets abreast of each other, and containing each a Hotchkiss gun, was evolved. The advantage of a second gun in action was evident when it was found that bullets hitting the single gun penetrated the water jacket and thus rendered the gun useless. On the other hand the extra weight of the double turret placed a load on the chassis, which was already loaded...
ARMOURED TRAINS—ARMOUR PLATE

203
to its full capacity in order to carry armour that would be proof against modern fire.

The use of the armoured car is limited to the roads, although in some seasons in open countries it is possible to operate over large areas of terrain away from the roads. Obstacles can hinder the progress of cars to a certain extent, but with determined and skilful drivers, and well-trained crews, there are very few roads over which cars cannot be taken. In civilised warfare the maintenance of large armies necessitates roads being kept open for wheeled transport, and once the line formed by the fighting troops is so arranged that there is very great scope for the employment of armoured cars if placed under the control of a skilful and enterprising commander.

At the outbreak of the World War in 1914 several well-designed types of armoured cars were produced, but the enormous demands for motor transport on the part of all the combatants to equip their rapidly increasing forces prevented the production and development of armoured cars in sufficient numbers to do effective work at the beginning of the war. During the fighting in the autumn of 1914 there were many opportunities for their use, and a few naval cars and some small units did very useful work in France and Belgium, but when the armies on the western front settled down to trench warfare the blocking of the roads prevented the further effective use of armoured cars on that front. The armoured cars that had been made were then sent to the distant fields of operation in Egypt, Mesopotamia, East and South-West Africa, while the detachment of naval armoured cars that fought in Belgium were employed in Rumania and southern Russia, where they were almost the only representatives of the British army in those countries. During the periods in which the contending armies were stationary and gathering their forces for the decisive contest there was no scope for the armoured cars, owing to the shell-torn roads, trenches and barbed wire, but the value of the armoured protection, mobility and fire-power of the armoured car contained the basis of the idea which was to have considerable effect on the latter phases of the war. In the stationary warfare of trenches the deciding factors were machine-gun fire, wire and mud. The armoured car could withstand the first by its armour protection, and could return it on equal terms with its own machine-gun fire. If it could be made to cross mud and wire the attack could then be made and the defence of trenches on more than equal terms. The best machine for crossing soft and broken ground at that time was the tractor with the endless steel belt, and by a compromise of the armoured car and the tractor the British tank was evolved (see TANKS).

Under peace conditions armoured cars form an essential part of most standing armies. As a means of policing the enormous areas in which the British army is responsible for keeping the peace the armoured car provides a unit which can be kept mobile, ready to move at the shortest notice, and can cover the greatest distances with the minimum fatigue and the maximum speed. It can only be exceeded in these respects by the aeroplane, but, unlike that machine, the armoured car unit can provide the armoured protection of a miniature mobile fort, equipped with machine-guns, searchlights, a plentiful supply of ammunition, food and water, that can hold its ground until a well-organized and well-equipped enemy has been assembled to meet it. In cases of civil disturbances, apart from armed rebellion, the armoured car provides a means by which the civil forces of the law can penetrate into the middle of a crowd in a way that would be impossible under ordinary conditions of police duty.

ARMOURED TRAINS.—In the earliest days of the application of railways to war uses, the idea presented itself both to inventors and to practical soldiers of utilizing the weight-carrying capacity of the railway and the pulling power of the locomotive for tactical as well as for strategic purposes. "Railroad batteries" figured in the American Civil War, and in the war of 1879; and armoured trains have appeared thereafter sporadically in most wars. Their utility, though it was confined within rather narrow limits, was unquestionable until the development of mechanical road transport. Nowadays, however, in countries where the rail system is sufficiently developed to give such trains real freedom of movement there exists an even fuller system of main roads on which armoured cars can operate, and in the World War period the fighting train has only figured in such theatres as those of the Russian civil wars, in which roads fit for heavy traffic are as a rule rarer than railways. As against the armoured car working on good roads the train must always suffer from being limited to certain tracks which are very easily interrupted by raids, air bombing, or artillery fire, and in such a future, as cars of the four-wheel drive or caterpillar type improve, the freedom of movement of the armoured car cannot but increase even in theatres of war in which roads are few. Considered as a self-contained fighting unit, therefore, it is improbable that the armoured train will be of much practical utility in the future.

On the other hand, the old "railroad battery" considered as a form of gun-mounting possessed, and more than ever now possesses, many intrinsic advantages over other forms of mounting heavy ordnance for field warfare. In the well-laid bed of a railway track, organized to distribute heavy strains equally, such mountings have their firing platform ready made, and the power of the locomotive gives heavy artillery a mobility that otherwise it would lack. In this form, then, the train represents the battery vehicles of horsed or motor artillery. The central member is the heavy truck carrying the gun, and the others are arranged for ammunition and for the accommodation of the gun personnel. Light armour is frequently used for the protection of the vehicles against shrapnel bullets, and in some cases the gun itself is provided with a shield. These railway mountings are referred to under ORD NANCE.

ARMOUR PLATE (see 2,518).—The history of armour plate during the years 1909-1914 differs from that of most other materials used in warfare, inasmuch as the period of greatest progress and activity occurred before the World War and was followed by a period of rest amounting almost to stagnation. The actual years of the war, which constituted a period of intensive culture as regards guns, shell, airships, aeroplanes, tanks, etc., added no stimulus to progress in the manufacture of armour plate. The efforts of British shipbuilders were devoted to the building of light, fast cruisers and destroyers for which there was urgent and immediate need, rather than to heavily armoured battleships which would take three years to complete.

During the years immediately preceding the war, however, the manufacture of armour plate had made steady progress, and the improvement in quality was marked. There were no radical alterations such as the employment of a new alloy steel, or the introduction of a new process of manufacture; but in the application of scientific principles to the details of manufacture, and the various heat treatments through which the plate passes, immense improvements had been made and were apparent in the quality of the finished plate. In this connexion it can be recorded that a long series of trials have proved beyond doubt that British armour made immediately before the war was greatly superior in ballistic qualities to that manufactured in Germany, in spite of the fact that the process of armour-plate manufacture originally came from Germany. For example, a German 12-in. plate was found to be no better than a British 9-in. under the same test, while a German 10-in. plate was only equal to the British 8-in. The plates tested were taken from the ex-German battleship "Baden," and are therefore thoroughly representative of the German product.

In Table I the average limiting velocity of penetration for British plates is taken to be 1,000 ft. per second in each case;
ARMOUR PLATE

the third column shows the comparative figures for German plates. The projectiles used at these trials were of similar mark and quality to those used in testing British plates of the same thickness.

In the case of the 400 and 480-lb. plates the actual limiting velocities were not reached, the projectiles, at the velocities indicated by the index figures, passing through the plates in a practically undamaged condition. Tests carried out on turret roof plates of 160-lb. and 200-lb. thickness also showed a marked superiority in favour of the British plates. These results may be accounted for to some extent at least by the fact that the manufacture of armour in Germany was a monopoly, and to all intents and purposes a State monopoly of sorts, whereas in Great Britain there were five rival firms of manufacturers and an Admiralty always asking for something better.

The necessity for improvement has been constant owing to the introduction of larger and more powerful guns—the 13.5-in. in the ships of the 1909-10 programme and the 15-in. in those of the 1912-3 programme.

Tables II and III, compiled from information contained in a paper read by Sir Eustace d'Eyncourt before the Institution of Naval Architects, show the increase in the thickness of armour on British and German battleships in answer to the challenge of the new guns.

Any increase in the thickness of armour presents very serious problems to the naval architect on account of the great additional weight to be carried, and it is therefore of vital importance that the quality of the armour should be of the best. It is not only in regard to increase in thickness, however, that progress has been made. The superficial area of plates has also been increased, and plates measuring 15 to 20 ft. in length and 10 to 12 ft. wide are now not uncommon. Large plates are in fact a necessity in modern battleship construction. The striking energy of a large shell is so great that the resistance opposed to it must be distributed over as large an area as possible. As an example of the forces involved the striking energy of a 15-in. shell at a range of 10 m. is 50,000 foot tons, or in other words its energy is equivalent to that of an express train weighing 250 tons and travelling at 60 m. an hour. There is grave danger, therefore, that a small plate, even if it succeeds in stopping the shell, may be driven bodily into the ship. Moreover, it is as true to-day as ever it was that the weakest point in any armour is the joint. A heavy shell striking a plate near an edge or corner is liable to break off and carry away a piece of the plate with disastrous results, and it is therefore desirable to eliminate this risk as far as possible by reducing the number of joints to a minimum, that is to say by increasing the size of the individual plates. At the present time the size of plate capable of being placed on a ship is only limited by the carrying capacity of the railways.

No substantial alteration in the process of manufacture of armour has taken place since 1910, and the description given in the earlier article in this Encyclopaedia requires neither modification nor addition. In other respects, however, much has been achieved, and some of the views held in 1911 require revision. For example, the statement that "plates sometimes vary considerably and are not of uniform hardness throughout" can scarcely be said to be true to-day, in spite of the great increase in size of modern plates over those made in the years previous to 1911.

It is impossible to discuss improvements in armour plate without at the same time taking into consideration the improvements which have been made in armour-piercing shell, and also the changes which have taken place in the nature of the attack. Conditions during recent years have been constantly changing. The introduction of capped projectiles, and the substitution of "up-angled" for "hacked" trials, each presented problems for the armour-plate manufacturer. Moreover it has only been possible to solve these problems by the laborious process of trial and error, for there is no exact knowledge on the subject, and theories (of which there are many) have proved sadly misleading. For example, the action of the cap has been, and still is, a subject for discussion. It was for some time believed that the action of the cap was only effective at velocities over 1,700 ft. per second, whereas actual experiment has proved that it is equally effective at velocities of 1,000 ft. per second and even less. Constant alterations in the shape, weight, and design, as well as in the quality of steel used in the manufacture of the cap, have further complicated the problem from the armour-plate manufacturer's point of view.

Interesting as the theoretical aspect of the subject undoubtedly is, there are at present too many unknown factors, both as regards shell and armour, to enable it to be regarded as an exact science; and recent experience has only served to confirm the statement made by an early authority, Maj.-Gen. Inglis, R.E., in 1880, that "in no subject that has ever been raised has mere opinion unsupported by practical experience proved so worthless as in this." For all practical purposes the thickness of the shell is limited by the necessary considerations of weight and cost, and this thickness is determined by the thickness of the plate it is to protect.

The thickness of the plate varies a good deal, as is shown by the tables, and at present it is common to use 50-lb. plates on the main deck of battleships and 100-lb. plates on the machinery deck. The thickness of the plates used on the upper deck of cruisers is usually 5 to 12 in., and on the lower deck 3 to 5 in.

Bullet-proof Armour.—While there was a hull in the activity of the manufacture of the gun mantle, there was still a problem of protection for the men who had to face the threat of the bullet. The introduction of a new material, in some cases a mild steel or cast iron, and filled with lead, breaks up fairly easily on a plate of hard steel; but the Germans soon discovered that if the bullet is removed from the cartridge and reversed (i.e. so that the bullet travels with the base or blunt end in front instead of the pointed end) it did not break up but punched a hole in the plate.

Every effort was made to defeat this attack, but it was found that even with the use of the best quality of alloy steel available a minimum thickness of half an inch was necessary to stop the reversed bullet at short range. All sorts of materials were employed, but steels were found to be the most efficient, and of these nickel, chrome, manganese, vanadium, molybdenum and zirconium, both singly and in combination, were all tried. The best results, however, were obtained from nickel-chrome plates, sometimes with an addition of one of the rarer metals.

While these experiments were being carried out in England the Germans were busy endeavouring to produce something
more satisfactorily than the reversed bullet which was only effective at short range. In this they were completely successful, and they produced the K or armour-piercing bullet. This consists of an outer envelope of mild steel of the same size and dimensions as the ordinary bullet. In the centre of the envelope is the bullet proper, made of hardened tungsten steel 30 mm. long, 6 mm. in diameter, and pointed at one end. The space between the envelope and the hard bullet is filled with lead. On striking a hard steel plate the outer envelope breaks up, but it and the lead lining appear to perform the function of a cap, and the hardened steel bullet perforates the plate.

At ranges up to 66 yd. with a good rifle, and more than this with a rifle in which the rifling has been worn, the armour-piercing bullet is not effective, owing to unsteadiness in flight, but at longer ranges nothing less than half an inch of the best steel is of any use as a protection against a direct hit at the normal. The action of the armour-piercing bullet, however, differs from that of the reversed bullet. The former is a clean penetration of the plate, whereas the latter punches a hole and removes a portion of the plate in the form of a small cylinder. Both at long and short ranges, therefore, a plate of at least half an inch in thickness was necessary to give any real protection. The weight of plates of this thickness weigh 20 lb. per sq. ft. It was obvious that a soldier could not carry his own means of protection in addition to a rifle and the other impedimenta which he took into action. It became necessary then to devise some mechanical method of carrying protection, and the combined efforts of many minds in this direction finally resulted in that weapon of offence and defence which was afterwards known as a "tank" (see TANKS). From the nature of the requirements it will be seen that the practice of the arming of the tanks was by no means an easy one. In the first place the plates in an untreated condition had to be soft enough to be easily machinable, while after treatment they were required to withstand the penetration of the armour-piercing bullet and the punching action of the reversed bullet. This necessitated a very hard plate, but on the other hand it was essential that they should be sufficiently tough to prevent cracking or the breaking off of portions of the plate even when struck near an edge or corner. In addition the plates were to be capable of being riveted to the body of the tank or to one another, and finally they must be of the minimum thickness, as the question of weight was all-important.

These requirements were met by the use of nickel-chrome steel, which possesses properties of hardness and toughness to a remarkable degree. Steel containing 0.3 to 0.5% of carbon with 3 to 4% of nickel and 15 to 20% of chromium was largely used, and in some cases improved by the addition of one of the rarer metals.

In view of the work which the tanks were designed to carry out it was of the utmost importance that they should be perfectly bullet-proof, and it is perhaps not generally known that every plate was tested by firing trial against the German bullet before it was built into the tank. Under this severe but necessary test a very high degree of excellence in the quality of the plates was attainable. The manufactured were subject to a series of tests which the plates were tested under Government supervision before they were dispatched.

(E. F. L.)

ARMSTRONG, SIR WALTER (1850-1918), British art critic and writer, was born in Roxburghshire Feb. 7 1850. He was educated at Harrow and Exeter College, Oxford. On leaving the university he became well known as a writer on art, and his judgment of pictures was considered of great value. From 1880 to 1892 he was art critic to various newspapers, among them being the Pall Mall Gazette, St. James's Gazette and Manchester Guardian. In 1892 he became director of the National Gallery of Ireland, a post which he held for more than twenty years. He was knighted in 1890. Sir Walter Armstrong was more especially an authority on the Dutch 17th-century and English 18th-century periods. He was the author of many works on art, of which the chief are: Gainsborough and his Place in English Art (1868); Sir Joshua Reynolds (1900); J. M. W. Turner (1901); Sir Henry Raeburn (1901) and Art in the British Isles (1900); besides Lives of Alfred Stevens, Peter de Wint, Gainsborough and Velasquez. He was also co-editor of Bryan's Dictionary of Painters. He died in London Aug. 8 1918.

ARMY (see 2,592).—In different sections which follow under this heading, the later history and organization of some of the powerful national armies which figured prominently in the World War are dealt with. In the articles on countries details of the post-war organization are given, and the object here is to explain the functioning of their armies in 1914-9.

I.—THE BRITISH ARMY

Command and Administration.—In 1910 the British army was commanded and administered by an Army Council, a system instituted in 1860. The Council consisted of the master-general of the army, the inspector-general of armies, the quartermaster-general of the army, the paymaster-general of the army, the adjutant-general of the army, the director-general of railways, and the director-general of aeronautics. The council was: the Secretary of State for War; the chief of the general staff (whose designation was altered in 1909 to that of "chief of the Imperial general staff"); the adjutant-general to the forces; the quartermaster-general to the forces; the master-general of the ordnance; the finance member of the Council; the civil member of the Council (later known—July 1916—as "under-secretary of State for War"); and the secretary of the War Office (as secretary). Outside the headquarters staff an inspector-general of the forces was appointed, whose duties were to review generally and to report to the Army Council on the practical results of the War Office Council; and for that purpose to inspect and report upon the training and efficiency of all troops, on the condition of fortifications and defences and generally on the readiness and fitness of the army for war. On Aug. 2 1910 the duties of the inspector-general of the forces were divided between the inspector-general of the home forces and the inspector-general of the overseas forces (the general officer commanding-in-chief in the Mediterranean). Both appointments lapsed on the outbreak of war in 1914.

The above constitution of the Army Council continued until the outbreak of the war, after which it was varied from time to time. The following are the dates of the chief of the Imperial general staff (Dec. 1915); the director-general of military aeronautics (Feb. 1916); the director-general of movements and railways (Feb. 1917); the surveyor-general of supply (May 1917). The director-general of military aeronautics, who was first appointed in 1913 directly under the Secretary of State, ceased to be a member on the institution of the Air Council on Dec. 21 1917. Another variation took place on Feb. 27 1918, when the permanent British military representative, British section, Supreme War Council of the Allied Governments, was added; but he again was removed on April 20 of the same year. The assignment of duties varied somewhat under the subsequent years in Council, but the general principles were as follows: Duties in relation to operations were allotted to the chief of the general staff; those relating to organization, disposition, personnel, armament and maintenance, to the adjutant-general; quartermaster-general and master-general of the ordnance; those relating to the Territorial Force Associations, the Volunteer Force and War Department lands, to the civil member; finance duties, to the finance member; transportation, to the director-general of movements and railways; business relating to the commercial administration of army supplies, not under the control of the Ministry of Munitions, to the surveyor-general of supply.

In more detail the responsibilities of the military members of Council were as follows: The general staff dealt with the preparations for and the execution of military operations, including the estimates of forces required, the organization and establishments of these forces from the broader aspect, also those connected with military intelligence and questions of staff duties, including training and education. The adjutant-general was responsible for all questions relating to personnel (except that of the Army Service Corps, Army Ordnance Corps, Army Pay Corps and Chaplains Department) and discipline, for organization, establishments in detail, mobilization, recruiting, discharges and for the control of the Army Medical Service. The quartermaster-general was responsible for supplies, transport, clothing and equipment (including personnel and organization), for movements, quartering, remounts and the Army Veterinary Service. The master-general of the
Ordnance was responsible for armaments, the manufacture of ammunition and for the Fortifications and Works Department.

In the organization of the armies in the field a partitioning of responsibilities similar to that arranged among military members of the Council was adhered to though some modification was necessary because the staff in the field was organized under three principal staff officers only:—The chief of the general staff, the adjutant-general, and the quartermaster-general; the military authority and the obligations of the ordnance officer were directed to the then TFT of G.H.Q. The major portion of the latter's duties in the field came under the control of the quartermaster-general, while the engineer-in-chief (a special field appointment) absorbed such of the duties of the director of fortifications and works as were required in the field. The quartermaster-general in the field controlled the paymaster-in-chief, and had the assistance of the financial adviser to the commander-in-chief, while the adjutant-general in the field controlled the Chaplains Department. It is noteworthy that it was not until April 1917 that the director-general of movements and railways was appointed to the Army Council, involving the removal of these duties from the quartermaster-general's control; a similar change was effected simultaneously in the field armies by the addition to the commander-in-chief's staff of an inspector-general of transportation, independent of the quartermaster-general. Similarly, the appointment of a surveyor-general of supply, anticipated by that of an additional civil member of Council to supervise army contracts in Dec. 1914, took, for coördination purposes, from the control of the quartermaster-general, the master-general of the ordnance and the finance member, such functions as related to the commercial side of the business of supplying the armed forces.

The military department concerned retained responsibility for design, specification and testing as well as for research and experimental work. The director of army contracts was brought under the surveyor-general of supply, and later there was added the director of ordnance works; the branch absorbed "the Armies' Munitions Requirements" from the Department of the Civil Member. A director of wool textile production was added in Dec. 1917, and in Feb. 1918 the Army Salvage Branch developed and was placed jointly under the quartermaster-general and the surveyor-general of supply. The only other appointment of interest is that of the military secretary. This office has always existed; at one time it was under the direct control of the commander-in-chief and later under the Secretary of State for War. The exact functions have varied from time to time. Broadly speaking, the branch, both in the War Office and at G.H.Q., in the field, dealt with appointments and promotions of officers, and to some honours, pensions, etc., for all ranks. Other changes which removed certain duties and responsibilities from the Army Council to newly formed ministries were effected by the creation of the Ministry of Munitions (June 1915), the Ministry of Pensions (Oct. 1917), and the Ministry of National Service (Oct. 1917). Thus, on its formation, the Ministry of Munitions took over responsibility for the supply of munitions, leaving the question of design to the War Office. About June 1915, however, the Ministry of Munitions in turn assumed responsibility for the manufacture of military equipment, and in so far as part of chemical warfare and trench warfare was concerned, and in the following Oct. it took over responsibility for design in other directions. The director of artillery became indeed nothing more than the military representative of the War Office and the Front, responsible for making demands—afflicting both design and supply—on the Ministry of Munitions.

In the original design for the military armarees in the field, the inspector-general of communications held the status of a command, but by a process of gradual absorption he eventually passed, except for defence duties on the lines of communication, under the control of the adjutant-general (field service units) and the quartermaster-general (for supply and maintenance).

It is unnecessary to describe in detail the organization of army headquarters in India, but it should be said that, so far as Indian army troops cooperating with British troops in the various theatres were concerned, the system of command and administration was generally similar to that described above, the chief difference being that the whole, ordinary and special, was organized into 105 battalions, which were each of them independent branches, working directly under the commander-in-chief. As for the dominions, Crown colonies and protectorates other than India, it had been unanimously thought at the beginning of operations that the organization of all the forces of the Empire should be assimilated as far as possible. In Canada there existed a permanent militia and an active militia, each serving a different purpose. They were divided into 17 mounted brigades, 10 brigades of field artillery, 23 infantry brigades, with the necessary ancillary services. In Australia a Military Training Act had been passed, rendering liable for service in time of emergency all males between the ages of 18 and 60, and imposing compulsory training in the militia on all males between the ages of 18 and 26. The permanent force comprised only three field, cavalry, and engineering divisions and 85 companies, and a nucleus of departmental services. This force, serving on a five-year engagement, and the militia forces, serving on a three-year engagement, were organized in both mounted and infantry brigades with establishments similar to those of the British army. In India the militia comprised 23 mounted regiments, 22 battalions of field artillery and 50 battalions of infantry, with proportionate ancillary services. In New Zealand all males between the ages of 18 and 25 were liable for service in time of war, those between 18 and 25 undergoing training and those between 25 and 30 passing to the reserve. The permanent force (sufficient only for instructional purposes) served for an eight-year engagement, and the territorial force, on a seven-year engagement, consisted of 12 mounted regiments, 9 batteries of field artillery, 9 battalions of garrison artillery and 16 battalions of infantry. In the Union of South Africa the permanent force on a five-year engagement consisted of five mounted regiments and five batteries of artillery. There were also a small coast-defence force and an active militia force, serving on a four-year engagement, comprising nine mounted regiments, four dismounted regiments, three batteries of field artillery, 12 battalions of infantry and the necessary ancillary services.

No other colony or protectorate maintained a force of any appreciable size, but all had some force of armed police or volunteers in some sort of military organization. In certain of the protectorates, such as East Africa, Nyassaland, Somaliland, Uganda, Gambia, Gold Coast, Nigeria, and Sierra Leone, there was a British or an Indian contingent, and in South Africa there was a body of the British and the Boers of the same calibre. The latter was discarded early in the war.

Forces Available.—Until the end of the 19th century the British forces, always limited by the expense entailed, were maintained for the following purposes: (a) Garrisons of trained troops for the outlying colonies and protectorates (including India); (b) a force available for the prosecution of punitive expeditions, or for the maintenance of order in those colonies and protectorates or on their frontiers; (c) the first-line defence of the United Kingdom in the event of invasion. The South African War, however, of 1899-1902 proved such a severe strain on home military resources that assistance offered by the self-governing dominions was gratefully accepted; and the rendering of this assistance marks a definite and important step forward in the military organization of the Empire as a whole. Owing to the trend of European politics at the beginning of the 20th century, the purposes for which the military forces were maintained underwent a definite change, and the organization—still limited by the costliness of a purely voluntary system of service—was subjected to a series of reforms based on the following possible requirements: (a) a small striking force capable of taking the field in Europe at short notice; (b) garrisons for colonies and protectorates (including India) and reinforcements for the prosecution of punitive and other campaigns in connexion therewith; (c) the defence of the United Kingdom against invasion during the possible absence of the striking force referred to above. This change in policy, due to the possibility of intervention in a European war, involved the absorption in the striking force of the whole of the regular forces serving at home, and thus the provision of additional organized forces adequate for defence against invasion became a vital necessity.

During the years 1910 to 1914, therefore, military effort was concentrated on the organization of this small striking force of regulars (which received the title of "Expeditionary Force") and of the Home Defence Force of territorial troops. The focus was put on the output of manpower, energy and experience on a small expeditionary force, and the consequent neglect of preparations to make use of the untrained masses of the male population capable of bearing arms, led, however, to a temporary paralysis of the powers of expansion. The regular expeditionary force was permanently organized in its field formations of divisions; and up to the outbreak of the World War no higher formations, such as army corps and armies, had been definitely organized, although the staffs and headquarter units for a general headquarters and two armies (or
army corps) were detailed to be formed on mobilization. In addition the lines-of-communication troops provided were calculated to a minimum, which in practice soon proved inadequate. As regards personnel, the peace establishments of the units comprising the force were, in the interests of financial economy, based rather upon the numbers required annually to provide the drafts necessary to maintain the strength of the garrisons in colonies and protectorates than upon the requirements of the Expeditionary Force when it should take the field.

As must be the case with any army raised and maintained upon a voluntary basis and paid as economically as possible, a constant and large percentage of the individuals included in the home establishments were "immature," either because their training had only lately begun or because they had been accepted when still youths with a view to their gradual development; so that in order to put this Expeditionary Force in the field it was always necessary that there should exist reserves not only sufficient to make up the difference between peace and war establishments, but also sufficient to replace the "immatures" included in the peace establishments and to provide replacements for early casualties up to 10% of the force. But, in spite of continued and varied campaigning, the British army had never been called upon to replace any great number of casualties; and therefore the necessity for providing numerous trained reserves in excess of those required for first mobilization, although foreseen, was not sufficiently realized by the country as a whole.

The actual organization maintained, then, during this period was as follows: (a) The regular army, which was in war, the force itself, the place in which it was maintained, one cavalry division (four to five brigades), six infantry divisions (with a minimum of lines-of-communication troops), and certain coast-defence troops (for home defence). To meet the deficiencies in personnel there existed: (b) the regular reserve, composed of men who had been fully trained by service in the regular forces; (c) the special reserve (known as "militia") until 1908, organized in units and composed of men who had merely received a recruit's training and subsequent annual trainings of 27 days in their special reserve unit, and certain skilled tradesmen who did not require and did not receive military training (these were not organized in units). The special reserve units proper formed the infantry of the coast-defence garrisons. It was further proposed that certain of these special reserve units (known as "extra-special reserve units") should be used as units (not draft-finding) either on the lines of communication of the Expeditionary Force or to relieve regular units on foreign service in order that they might join the Expeditionary Force, should it be so desired. (d) The Territorial Force, organized in 14 mounted brigades, 14 infantry divisions and certain coast-defence troops. Being designed for home defence only, the peace establishment of the Territorial Force was intended to be that at which it would take up its defence duties in war. And not only was the strength of the Territorial Force seriously deficient, but much of the personnel were inadequately trained, and, moreover, included a large percentage of men who were too old or too young or physically unfit for active campaigning. The Territorial Force Reserve was so weak as to be negligible (661 officers and 1,421 other ranks on July 1, 1914).

Other forces which existed or came into being during the years 1910 to 1914—which may be termed the preparatory period for the World War—were, in addition to the Territorial Force Reserve: (a) the Territorial Reserve; (b) the Veteran Reserve. When these forces were first formed in 1910 they were intended to be part of the Territorial Force Reserve, but in 1911 they were reorganized, and the Territorial Reserve was reclassified as the former of these two. In 1912 the other reserve, retaining its separate existence, and the Veteran Reserve being renamed the "National Reserve." Neither of these forces had any definite liability for service unless undertaken by individuals. In addition there were certain other technical services. The Technical Reserve were to supply expert and skilled workers to assist the national forces in time of national emergency. For this purpose there were registered a number of certain classes of workers who were eventually attached to the Expeditionary Force, the larger number, however, being utilized at home. The "Voluntary Aid Detachment" scheme also was instituted as part of this reserve, and in accordance with the Geneva Convention. Originally designed to supply the personnel for "casualty clearing stations" it was finally used for the purpose of supplying personnel (mostly newly female) for military hospitals at the British Expeditionary Force. Each individual taking service on a personal engagement. The organization also provided and maintained a considerable number of hospitals and convalescent establishments at home.

Training of Youths. Cadet units had been in existence for many years as a part of the old volunteer system, and broadly divided into two classes: those raised and maintained by universities and schools, and those raised and maintained locally at the expense of individuals. On the formation of the Territorial Force the former class were formed into Officers' Training Corps, and in 1908 were removed from the jurisdiction of the Territorial Force Associations and came directly under the War Office. The latter units, however, were taken over by the Territorial Force Associations. The Officers' Training Corps existed primarily to provide officers for the special reserve and the Territorial Force; they were divided into senior and junior divisions, and were immediately passed to the Reserve. They were universities. Members of these corps could obtain a first certificate in either division, but the second, and qualifying, certificate could only be obtained in the senior division. The number of O.T.C. contingents in 1910 was 171 and in 1913, 182; but the numbers composing the units had increased in 1913 to 25,208. That efficiency was also growing is shown by the fact that, in 1910, 2,665 certificates were obtained, and in 1913, 8,393—the attendances at Annual Camp in each year exceeding 10,000.

In 1910 there were 340 officers commissioned direct from these O.T.C. and 2,637 from the Regular Army. During the war period the Officers' Training Corps were continued, and considerable use was made of their personnel in supplying the deficiency of instructors for the formation of the new armies and also in meeting the grave shortage of junior officers throughout the regulars, territorials and new armies. The normal work of the corps—more especially of the senior division in granting certificates and supplying officers for the Territorial Force and special reserve—continued throughout 1915; but at the end of that year those members who attained 18 years of age were called upon to be attested as privates, and were, however, continued as members of their O.T.C. until the age of 19, when they were summoned to the Colours. This continuation of their training enabled them to be rapidly brought forward for commissions, if duly recommended by their O.T.C.

The cadet units provided for the training of boys with a view to their eventually joining the ranks of the Territorial Force, and for their inclusion in organized cadet units. The O.T.C. were attached to the new unit and the appropriate Territorial Force unit. In 1910 there were 94 such cadet units, comprising 53 companies, rising gradually to 258 units, comprising 858 companies, in 1914. During the war, a very large increase took place, there being as many as 1,005 cadet units, comprising 1,007 companies, with a total strength of 41,108; which in 1919 had risen to 559 units of 2,464 companies, with a total strength of 102,500 cadets. Though by no means an Officers' Training Corps, the 29th ages, of the Boys' Legion (Artists' Rifles) was in Dec. 1914 selected by the commander-in-chief to act as an officers' training battalion for the armies in France; it was withdrawn to the neighbourhood of general headquarters, and to it were attached for training all candidates for commissions from the ranks of the Territorial Force units in the field.

During 1916 the deficiency in officers became even more acute, and the need for organizing a cadet school was clearly established in France; in which N.C.O.'s and men selected from units actually in the field were trained with a view to their obtaining temporary commissions. Simultaneously the Army Council decided that in future—except in certain technical branches—no temporary special reserve or Territorial Force commissions would be granted to any candidate who had not passed through the ranks of a cadet school (latterly designated the "special reserve") or who had not been in 1915-19 or in the military experience as an officer. This necessitated the formation at home of a number of cadet battalions specially designed to prepare candidates for commissions. They must not be confused with the Officers' Training Corps of the old volunteer system, which were eventually assigned to the Expeditionary Force, the larger number, however, being utilized at home. The "Voluntary Aid Detachment" scheme also was instituted as part of this reserve, and in accordance with the Geneva Convention. Originally designed to supply the personnel for "casualty clearing stations" it was finally used for the purpose of supplying personnel (mostly newly female) for military hospitals at the British Expeditionary Force. Each individual taking service on a personal engagement. The organization also provided and maintained a considerable number of hospitals and convalescent establishments at home.

Organization. Certain of these units in the regular army itself took place immediately prior to 1914. The system of communication was greatly improved by the formation of signal
companies, Royal Engineers (telegraph, telephone, visual and despatch-riding). One such company was allotted to each division, the headquarters section being with divisional headquarters, and a section with each infantry or cavalry brigade headquarters, until supplying their own signallers for internal communication. In the field artillery 2 howitzer brigades and 6 divisional ammunition columns were added, the result being that each of the 6 Expeditionary Force divisions was provided with a complete howitzer brigade of 3 batteries, in place of the brigade of 2 batteries which had hitherto existed. In consequence of these additions, an increased number of artillery reservists were required for mobilization; and to provide them a certain number of recruits for field artillery were taken for a short period of Colour service in order that they might be rapidly trained and passed to the reserve. In this way it was possible to strengthen the number of special reservists of the field artillery, and the training brigades hitherto maintained for these special reservists became available to form the divisional ammunition columns on mobilization. The number of field-artillery depots was increased from 4 to 6. The infantry organization was also altered from 8 to 4 companies per battalion. This reorganization had not taken place in the Territorial Force when mobilization occurred, but was then introduced. A complete revision of the system of supply and transport in the field was also made. The divisional train system (organized in 4 companies, each composed of a technical headquarters and the baggage and supply wagons of units, manned by Army Service Corps drivers) was introduced, and the chain of supply to railhead was completed by the introduction of a mechanical transport supply column of 3-ton lorries for each division. This unit, plying between railhead and the refilling point, daily refilled the supply wagons of the train. The cavalry division did not form a train but was served by two mechanical transport supply columns of 30-cwt. lorries delivering on alternate days. The supply of ammunition was organized in a similar manner, the divisional ammunition column (horse-drawn) refilled units and was itself refilled from railhead by a mechanical transport ammunition column (one per division). (For the Flying Corps, see the article under that heading.)

In the organization adopted for war the division was designed to be the tactical and administrative unit, self-contained in that it was composed of all arms (except the Flying Corps) and was provided with all the ancillary services required for its maintenance in the field. This system obtained throughout the British armies during the war, the divisions as self-contained units being allotted to army corps as occasion required, and these in turn to armies; the only deviation was in the case of the Australian and the Canadian army corps, in which the corps was designated a division, and in certain respects became the "unit of administration." The division in detail consisted of: headquarters (including the commander and staff, the commanders of artillery and engineer troops and the directors of medical, veterinary and ordnance services); 3 infantry brigades — each of 4 battalions, reduced in the winter of 1917–18 to 3 owing to shortage of personnel; 4 artillery brigades — each of 3 6-guns batteries (three batteries were 18-pounder guns and one was 4.5-in. howitzers); one heavy battery and ammunition column — four 60-pounder guns, horse-drawn; one divisional ammunition column (carrying ammunition for all arms); 3 field ambulances — each comprising bearer and tent divisions; 2 field companies Royal Engineers (a third added later); one signal company R.E. (sections distributed to headquarters of divisions and infantry brigades); the divisional train (carrying baggage and supplies and executing all supply arrangements between refilling points and the troops themselves); one mobile veterinary section; one cavalry squadron (withdrawn almost immediately to reinforce the cavalry corps). Thus it had a strength (excluding details at the base at the rate of 10% of strength) of 585 officers, 17,488 other ranks, 5,959 horses, 76 guns, 2, machine-guns. The organization of a cavalry division followed the same lines, but comprised 4 brigades each of 3 regiments, in place of 3 brigades each of 4 battalions in the infantry division. The strength (excluding details at the base at the rate of 10% of strength) was 430 officers, 8,830 other ranks, 9,815 horses, 24 guns (13-pounder), 24 machine-guns.

Administration of Personnel.—The record of services of all personnel (except officers) together with necessary personal details was carried on a card of the "personal record" offices. In these offices were filed the original attestation forms, on which all "casualties" affecting the rank and file (e.g., promotion, postings, transfers, and discharges) were entered. Other original papers (appointments, and details of marriage, children and next-of-kin) were entered on receipt of the notification of the "casualty" from the unit concerned. This system continued in war as in peace. All such records as war, however, passed through the 3rd echelon of general headquarters of the theatre and were also entered on a special war army form which followed the individual throughout his service during the war period. By this means general headquarters staffs were enabled to take a detailed account of all personnel of the Force, and the War Office was kept informed of the total number of personnel engaged, the numbers of officers, N.C.O.s, and rank and file engaged, the number of "casualties," the number of "deaths," the numbers held in each place of detention and in each prison, etc.

Payments to officers were made through agents (bankers), and special army cheques made out by an officer could be cashed within defined limits by field cashiers accompanying the troops. Payments to men were reported on "acquittance rolls" and entered in the personal pay book carried by every man. These payments— together with credits, counter-charges and claims received from any source or resulting from casualties reported to record offices— were matched by the receipt of the passing officer in charge of the accounts of the men affiliated to each record office. This system, prepared shortly before the outbreak of war and first tested therein, obtained for all theatres except India and Mesopo-
tamia, and proved very successful—the maximum personnel engaged at any time being 1,942 directing staff (of whom 250 were females) and 44,076 subordinates (of whom 30,000 were females).

Mobilization.—Preparations for mobilization had received most careful and detailed consideration during the years immediately preceding the war; and it may be truly said, in respect of the Expeditionary Force, that when mobilization was ordered in Aug. 1914 everything was ready "down to the last garter button." These mobilization preparations were confined entirely to that Expeditionary Force; the embodiment of the special reserve and the Territorial Force being merely a calling-up of existing personnel and not in any sense a "mobilization." The stages in the prepared plan of mobilization were minutely followed, and comprised, first, the initiation of what was termed the "precautionary period," followed almost at once by that termed "general mobilization." The "precautionary period" scheme was based on the necessity for defending the United Kingdom against the possibility of invasion or raids—a primary danger in the case of an island power. For this purpose the role of the navy was of first importance; and defence was required for all harbours and dockyards called into use. This was secured by the introduction of personal service, and was brought about by the general introduction, throughout the country, of its ancillary services of electric lights, etc., should be immediately placed on a war footing—the personnel being called up by regular reservists who, on the first day of mobilization, joined the units detailed for standing defence duties. These units again were augmented by units of the special reserve and Territorial Force accustomed to train annually at the defences for which they were intended and which they actually manned at the outset of the "precautionary period." The mobile force associated with these defences was in the first instance formed of infantry and artillery and as peace garrisons, reinforced temporarily in many cases by detachments of serving personnel from units stationed farther inland and actually mobilizing. On the embodiment of the Territorial Force, certain of its units proceeded, according to programme, to their coast defences (known as their "war stations"), thus replacing units of the regular army temporarily forming mobile garrisons but actually destined for the Expeditionary Force; these Territorial Force units were sufficient not only to form the garrisons, but also to furnish small mobile columns. Later, certain of these units—chiefly those detailed for fixed defences were in the places to which they were permanently destined to defend their allotted coast defences or "war stations" after embodiment at depots, where they had spread their Expeditionary Force
personnel and absorbed any surplus regular reservists and sick and immature men of the mobilized regular units. In addition to the manning of the coast defences, certain vulnerable points—e.g. possible landing-places for small raiding-parties, cable landing stations, wireless receiving stations, vital railway bridges—required watching or protection at the inception of the precautionary period. This was undertaken as an additional obligation by the special service sections of the Territorial Force, each being allotted a particular war station. Those units of the Territorial organisations which were not absorbed either at once or after relief by the special reserve units in coast defences, were assembled for training in their infantry divisions and mounted brigades; and preparations were completed for their rapid conveyance to any threatened point.

In actual fact a slight variation from the original scheme was made for a few days in respect of the disposition of the 4th Regular Division of the Expeditionary Force. This division, whose normal peace stations were in Woolwich, Shorncliffe, Dover, Chatham and Colchester, was ordered on the third day of mobilization to send small forces of infantry and artillery to Norfolk, York division only being left in its home station. It later moved to Bury St. Edmunds, and took over for some days the command of the east coast (excluding coast defences), until a Territorial mounted division was sufficiently organized to release the 4th Division for the Expeditionary Force in France. Similarly, the 6th Division from Ireland was brought over to England and assembled as a support to the Territorial formations guarding the east coast. This division, an integral part of the Expeditionary Force, was retained at home for this defensive purpose until the beginning of Sept. and only then followed the Expeditionary Force, joining it on the Aisne. General mobilization was, therefore, confined to the regular units comprising the Expeditionary Force.

To deal first with personnel. As a constant preparation for mobilization, each unit during peace compiled twice yearly a mobilization form, showing the personnel actually available with the unit, less those required for duty elsewhere and those immature or insufficiently trained for the field. This form was passed to the record office concerned, which, after stating the number of reservists detailed for the unit and its first reinforcements (which invariably accompany it overseas), and any deficiency or surplus of reservists, passed on the form to the War Office for investigation and information. The only action taken in the War Office was to detail the requisite number of officers from the reserve of officers and special reserve for posting to the units of the expeditionary force. The posting of officers, as shown by the movement of posters and individual notices summoned all reservists to rejoin the Colours—those of cavalry and artillery to allotted depots; those of infantry to regimental depots, where they were clothed, armed, and equipped for service; special officers were attached as advisers to units, the rest remaining at depots for incorporation in special reserve units in course of embodiment. Those of other arms rejoined their units direct, there to be clothed, armed and equipped; any surplus or deficiency being adjusted by their corps depots, where the surplus unallocated reservists rejoined. As regards matériel, each unit of the Regular Expeditionary Force (with the exception of certain mechanical transport units of the Army Service Corps) possessed the mobilization vehicles, arms and equipment required to pass from peace to war scale; and it was merely a question of issue and taking into use. As regards horses, the whole system had undergone the supreme change just in time for actual mobilization. This system was that commands made a classified census of suitable horses available among the civil population. Any surplus over and above that required by units mobilizing in one command was transferred to the War Office. The War Office had made an organized survey of the country, and commands—e.g. the Aldershot command, which has practically no territorial area, obtained most of its horses from the London district, which mobilized very few troops. The system involved selection for the horses, but the loyal cooperation of inhabitants in voluntarily bringing their horses to named centres to a certain extent overcame this defect. Certain large farms had for some years been keeping horses for the reserve cavalry, the horses being placed in the hands of the officers of the war office in case of emergency a given number of horses of specified classes suited to military requirements.

The War Period.—Owing to the special conditions of warfare which prevailed from 1914 onwards, to the progress of inventions, and to the variety of theatres in which operations took place, the standard organization of the original Expeditionary Force proved inadequate to meet the various requirements. It is, however, noteworthy that the structure of the infantry division—the main basis of organization—remained substantially intact, though the strengths and the proportions of arms and services underwent modification, according to changing conditions and the special needs of certain theatres. Thus, to the divisional organization were added, for example, an employment company and a salvage section.

Royal Engineers.—In the later stages of the war the need—in connexion with artillery-rangiing—for more accurate ground sur-veying in the field was met by the formation of three field survey companies—employed prior to mobilization by the Board of Agriculture and Fisheries on the continuous survey of the kingdom. These were augmented eventually to three battalions, France receiving one per army and other theatres a due proportion. These included specialist sections termed topographical, map, observation, sound-ranging and meteorological. In the course of the war various special units were formed, 25 special "tunnelling companies," recruited from coal-miners, were formed, each with an establishment of 14 officers and 307 other ranks. This was later raised, in the case of all but 5 companies, by 4 officers and 223 other ranks per company, by the attachment of infantry working parties.

Artisan works companies to the number of five were formed in France for the construction of huts and other engineering work. Eleven forestry units, for the purpose of obtaining timber in France, were raised, and in addition a considerable number formed in Canada were employed in France, Scotland and Wales. Seven army signal companies were selected, and formed at the War Office for the organisation of wireless, to train, maintain and operate trench tramways and light railways, and these eventually became transportation (R.E.) units. A "military works" or "headquarters" company (Camouflage Park) was formed in 1916 and operated throughout the allied armies. A small infantry section was formed in France in 1918.

Chemical Warfare.—After the German gas attack at Ypres in May 1915, at first there was a reluctance to utilize this weapon on a large scale among officers who were to be concerned with the use of this new lethal weapon. The first special company of the Royal Engineers was formed for the purpose in July 1915, and numbered 186, and three companies were in existence by Sept. of that year, taking part in the battle of Loos. Rapid progress continued; during the winter 1915-16 the 4-in. Stokes mortar and an improved flame-thower were developed, and in 1917 a special companies of special brigades R.E., each composed of a special (cylinder) company R.E., with an establishment of 8 officers and 250 other ranks, a special (mortar) company R.E., of 18 officers and 310 other ranks, and special sections R.E., (for flame-throwers) which, however, were never fully equipped or up to strength, the use of this weapon being soon abandoned. During 1917 this organization was again revised, and each of the five armies then in existence in France was provided with a headquarters special company R.E.—the various technical companies being allotted as required by the tactical situation.

The above was the organization for offensive action. Defensive measures were provided against gas by the establishment of the army medical services; and in June and July of 1915 specialist officers were appointed to the headquarters of each army, where anti-gas schools were established. These officers were at first called "medical advisers." In March 1916 specialist (chemical) officers were appointed to all divisional headquarters where anti-gas schools were established. The special brigade R.E. also provided non-commissioned officers to infantry brigades for the purpose of checking the fitness or otherwise of the respirators and for supervising the general state of gas defence. In March 1917, chemical advisers were appointed to each corps headquarters. The gas services eventually expanded to a total of 490 officers and 6,875 other ranks.

Army Service Corps.—In the original Expeditionary Force the ratio of guns to infantry was approximately 6 per 1,000 rifles, but as the war progressed so did gun-power show a marked increase; and whereas in Aug. 1914 Royal Artillery personnel was 11,808, by March 1917 it had increased to 58,780. Taken in detail the horse artillery made but slight increase, the number of batteries rising from 26 to a maximum of 28 in 1918; field artillery increased from 153 to a maximum of 722 batteries in 1917. This number, however, was subsequently reduced to just over 600 6-gun batteries by the assimilation of a certain number of 4-gun batteries. A considerable reorganization took place later when the field artillery was divided into divisional and reserve batteries. The Royal Garrison Artillery, which manned the medium and heavy guns and howitzers as well as the few mountain batteries, the number of heavy batteries being reduced from 70 to 15, and many of the 442 mountain batteries from 3 to a maximum of 425 in 1917; mountain batteries from 9 to a maximum of 17 in 1918. Anti-aircraft sections, non-existent in 1914, reached a maximum of 275 in 1916. Trench mortar batteries, first formed in 1916, reached the number of 142 in 1917.

Machine-Gun Corps.—In the autumn of 1915 the formation of the Machine-Gun Corps was decided upon. Originally consisting in
separate companies, the corps was reorganized in the winter of 1917-18 on a battalion basis. Eventually one machine-gun battalion was added and the tank and some other companies were withdrawn. A battalion comprised 4 companies, and a company consisted of 4 sections each of four guns (total 64 guns). A portion of this corps — the Tank Corps.—In June 1916, the heavy section of the Machine-Gun Corps in France was organized in six companies as the nucleus of the Tank Corps. Each company consisted of 4 sections, each of 6 tanks; and three "tank workshops," the personnel of which were transferred to a company. The crew of a tank was one officer and seven other ranks. In Sept., of the same year expansion was decided upon. An administrative branch was to be formed in England and a fighting branch in France. By the end of 1916, 4 companies of tanks were in action as the tanks became available. At the same time 2 companies were formed in England with the intention of their development into 5 battalions. In April 1917, 2 battalions were grouped in 2 brigades, and in April 1917, the 3rd brigade of 2 battalions was transferred there from England. Expansion continued, and in June 1917, the title of Tank Corps was definitely bestowed on the corps.

In April 1918—after various vicissitudes and delays, due sometimes to difficulties of manufacture and sometimes to shortage of personnel—a portion of the corps was formed into armoured car battalions; and at the time of the Armistice a total of about 1,600 tanks was in action on the Somme front. In March 1918 a separate corps was organized on a permanent basis, and in May 1918 a Tank Corps was formed in France, and in June 1918 another Tank Corps in England. The number of tanks in service at home on 1 November 1918 was 6,000; at the Armistice, 20,000. As on land, so in the air, the successes of the Tank Corps were of immense value; the scaling of the Hindenburg Line, the breaking of the Hindenburg Line itself, the capture of Cambrai, the crossing of the Seine and the capture of the city of Paris, and the occupation of the Frontiers of France were attributable to the small and efficient fighting party known as the Tank Corps. By October 1918, when the Armistice was signed, there were 67 divisions of the British Army in France; the Tank Corps, with about 2,000 tank engines, comprised one division (36 battalions). The Tank Corps, therefore, had played a vital role in the Allied victory. It had proved itself to be an indispensable weapon in modern war and had contributed to the downfall of the German Empire.
pared with about 60 in 1914. During the war daily feeding strengths in the United Kingdom at its height amounted to 45,000 men and horses, and to meet these numbers the daily tonnage in foodstuffs was 11,000 tons, and in forage 8,000 tons. To ensure this maintenance, supplies were drawn from every quarter of the globe, a feat made possible only by the enormous increases in the efficiency of transport and storage, and the provision being made months ahead, so that a steady flow to the various theatres of war could continue with the minimum of interruption. Furthermore, it was estimated as far as possible to avoid the purchase of meat stores, or increase the existing accommodation for frozen meat, and develop the local resources of each theatre to the fullest extent, with the view of economizing shipping. The Army Service Corps also embarked on the establishment of large numbers of catering units to provide fresh bread, rolls, butter, pies, bread-and-butter, puddings, potatoes, vegetables, fruit, meat, fish, and poultry as well as stores of gunpowder, petrol, and the necessary provision of tinplating and case-building for cabling and packing.

**Army Ordnance Services.** — In 1910, and onwards till 1914, the ordnance services of the army were carried on by a staff of 251 officers and 2,341 other ranks, reinforced by some 4,900 civilian subordinates. The "other ranks" were formed in 9 companies of widely varying strengths, and in a number of small detachments distributed throughout the army. The holding of bulk supplies of ordnance stores and clothing was restricted to Woolwich and Pinlicio respectively. To these two places were consigned the stores and clothing managed by the Store Detached Corps, which was formed by the Army Service Corps and the Royal Military Colleges. The stores and clothing were consigned to these companies by the Army Service Corps and Royal Military Colleges, and from them distribution was made to the local ordnance depots for issue to the troops. Reserves of warlike stores and clothing for one cavalry division, one cavalry brigade and 6 infantry divisions, 1,000 men, were consigned to each of these companies. The density of distribution was increased as the war developed, and the distribution was generally increased, with the result that maintenance was maintained almost exclusively to confined to functions on the lines of communication. The personnel allotted to the front area was limited to a deputy director of the department, a deputy-director with each division, and a warrant officer with each brigade. The director of ordnance services was to be on the staff of the J.G.C. lines of communication. The new company system was replaced by the Army Service Corps and by the Royal Ordnance Corps, which was formed by the Army Service Corps and the Royal Military Colleges. This force was divided into 2 sections, each with an establishment of 2 officers and 164 other ranks, additional officers being allocated according to the number of companies mobilized. When, in Aug. 1914, the country required the best men, the force was increased to 4 companies with 32 additional officers accompanied it to the bases, where these officers reserved of stores and clothing were dispatched the war reserves of stores, and the rapid expansion of the army in the field, and the multiplication of various expeditionary forces in widely separated parts of the globe, not only called for great increases in ordnance personnel, but also revolutionized the organization of the services in the field. The main line of action was to modify the functions of, and by the necessary fortification of, the principle of an ordnance officer with a division to an ordnance organization with the headquarters of each corps and army. Moreover, the immense use made of artillery throughout the campaign called for the establishment of an entire army of officers engaged in the main functions of which were to bridge the gap between the artillery front and the large workshops at the base. These workshops, which were all机械化, organized, were to cater for all lines of work, light and heavy, their nomenclature indicating the nature of the repairs to be undertaken, as well as their relative degree of mobility. Though frequently "shifted" to meet any particular set of circumstances, they were organized on a scale of two light per three divisions, one medium per corps and one heavy per army. The value of these mobile shops will be the better appreciated when it is stated that for them something like 15,000 guns and carriages would have had to be relegated some distance to the rear, if not to the base, for repair.

At the date of the Armistice there were in existence 60 of the light, 25 of the medium and 6 of the heavy gun workshops, the shops at the rear being attached to the railway depots, ammunition sections, and officers' clothing depots, where there were added to the normal organizations on the lines of communication institutions such as schools, workshops, and workshops, auxiliary, repair depots and repair factories and repair depots at the bases. The effect of this wide expansion of ordnance functions and of the magnitude of the operations in the different theatres of war was to call for a very great increase in the personnel engaged, and in the case of the clause employment was from the commencement offered to retired officers, who, taking over the work at home, released the active officers for service abroad. As soon as its work was complete, they were given as many as possible of these charges, which was set on foot to obtain "temporary" officers from suitable professions in civil life, and to train them in ordnance duties. As for the other ranks, large numbers of pensioned warrant officers and of the officers of the corps of ordnance were taken on for the services, the remainder required being obtained by direct enlistment. At the date of the Armistice 2,342 officers and 38,193 other ranks were doing duty with the ordnance services, in 144 companies and other formations. The majority of this personnel was serving overseas; the balance were at the home depots, where they formed part of a mass of experienced labour, which reached a maximum of 48,000, nearly one-half being women.

Turning to the store side of the matter, the original war reserves were hardly exhausted, and it became necessary to evolve new supplies to meet the demands of the war. In many instances in the early days supplementary provision being made months ahead, so that a steady flow to the various theatres of war should continue with the minimum of interruption. Furthermore, it was estimated as far as possible to avoid the purchase of stores, or increase the existing accommodation for frozen meat, and develop the local resources of each theatre to the fullest extent, with the view of economizing shipping. The Army Service Corps also embarked on the establishment of large numbers of catering units to provide fresh bread, rolls, butter, pies, bread-and-butter, puddings, potatoes, vegetables, fruit, meat, fish, and poultry as well as stores of gunpowder, petrol, and the necessary provision of tinplating and case-building for cabling and packing.

**Expansion.** — No plans existed in 1914 for the expansion of the regular forces, beyond the automatic embodiment of the special reserve units. These were already included in the scheme for Home Defence, with the exception of certain extra-special reserve units which were earmarked for other service. The only step taken towards expansion during the mobilization period was to withdraw prior to embarkation 3 officers and 8 non-commissioned officers from each infantry unit of the Expeditionary Force. The next step was to call home regular units from overseas garrisons, relieving them by extra-special reserve units and territorial units who volunteered for the duty. These regular units on arrival from overseas were reorganized. The additional mounted brigades which formed a part of the additional troops enabled the cavalry to be reorganized as a corps of 3 divisions, each of 4 cavalry brigades. The 5 additional infantry divisions were completed as to other arms by the mobilization of artillery and engineer units existing at home, surplus to the Expeditionary Force; but horse artillery and fortress engineer companies had to be used in some instances to make good deficiencies. Lord Kitchener, on assuming control as Secretary of State for War, at once grasped the need for immediate and immense expansion, but there remained no regular army to which to call, and three routes had to be taken to meet the emergency: (a) to expand the special reserve, which was partially regular owing to the inclusion of the regular depot establishments; (b) to use the Territorial Force organization, which provided a framework of 14 mounted brigades and 14 infantry divisions; (c) to
create entirely new formations. The objections to the first course were that it would disorganize the maintenance organization (the special reserve) of the regular forces already engaged in the campaign, that the number of special reserve units was too small and that they consisted of practically nothing but infantry. The main objection to the second was the inadequacy of the framework upon which to construct the necessary 100 infantry divisions; duplication and reduplication of these small nuclei would eventually entail practically new formations; their duplication and reduplication for dilution by the inclusion of the untrained manhood of the country would render them immobile and temporarily disorganize them for any purpose whatsoever. H. H. Kitchener would thereby be paralyzed and the possibility of using any units already existing and organized for reinforcements would be neutralized. Lord Kitchener therefore decided to create new divisions forthwith, retaining the special reserve for its maintenance functions and simultaneously fostering the training and recruiting (and eventual duplication) of the Territorial Force in order to relieve regular army units in garrisons overseas and to supply immediate unit reinforcements to the field army; and further, as soon as the territorial divisions, not broken up for the above two purposes, were sufficiently trained, to put them into the field as complete divisions. The new divisions (units created as armorial bearings under Kitchener’s armies), each of 100,000 men; and the nucleus of the I. New Army was at once commenced by forming the unit organization of 6 divisions (numbered 9 to 14) and drafting into them the necessary personnel. The II. and III. Armies began to form in Sept. 1914 and comprised the divisions numbered 15, 17, 18, 19, 20, 21-26 and 37. The IV. Army (30th to 33th Divs.) began to form in Oct. and Nov. but never took the field in divisions, being converted in April 1915 to draft-finding duties. The V. Army (Divs. 16, 36, 38, 39, 40 and 41), began in Dec., eventually took the divisional numbers of the IV. Army. The Territorial Force of divisions had to relieve regular troops overseas were the 1st Wessex, 1st Home Counties and 2nd Wessex. These were never re-formed as divisions. Units of the W. Lancs. and 1st London Divs. used as unit reinforcements to the Expeditionary Force in France, were eventually reassembled in their divisions there. Those who took the field later as complete formations did so at first under their territorial designations but were eventually numbered so that the final divisional enumeration of the Field Army Divisions included all regular, territorial, New Army, Indian (embracing British and Indian native units) and Indian subjects. Recruiting During the War.—With the exception of a certain number of officers (who had had experience in the army and in many cases experience of minor campaigns) and of a certain number of older men whose period of army and reserve service had expired, there existed no reservoir of men who had undergone regular military training to arms, owing to the fact that the army had always been maintained by voluntary enlistment. This was a considerable handicap; but, on the other hand, the fact that a number of ex-officers and older men had had previous campaigning experience was an advantage, though, of course, they were insufficient in numbers to deal with the man-power of the nation as a whole.

Directly mobilization was ordered voluntary recruits offered themselves in such numbers that the recruiting machine was for a time paralyzed and unable to deal with the applicants. The intake, which, prior to the outbreak of war, was from 70 to 80 per day, rose immediately to 6,000 per day from Aug. 5 to 22; to 6,000 per day from Aug. 22 to 30; and by Sept. 3 it had reached 33,000 per day. On Sept. 10, owing to lack of accommodation in barracks and deficiencies in stores and equipment, the standards had to be raised considerably. This was correctly interpreted as meaning that the urgent need for men was over; and the numbers fell to 2,500 per day. On Nov. 6 the standard was again lowered, and recruiting rose to 3,000 a day.

Towards the end of the year—when it became evident that more men would be required—a parliamentary recruiting committee was formed, and a recruiting campaign was undertaken throughout the country, resulting in an intake of some 60,000 men. In July 1915, a National Registration Act was passed, and the Local Government Board were allotted the task of supplying the particulars of all males between the ages of 18 and 41. From these, registers were compiled in various recruiting areas; and in Oct. 1915, the “Derby Scheme” or “Group System” was initiated by Lord Derby on his appointment as Director-General of Recruiting. Under this system men were to be enlisted for one day and immediately passed into the reserve with liability to be called to the Colours when required. Between Oct. 25 and the middle of Dec., 2,000,000 men were attested under this system, of whom 50% were married men; and the Government had given a pledge that single men would be called up before married men, and it became clear that the single men of the nation had not responded, it was decided to introduce compulsory service.

The first Military Service Act received the royal assent at the end of Jan. 1916, rendering liable for military service all single men between the ages of 18 and 41; and calling to the Colours under this Act commenced on March 3. The Act was later extended to include married men, who began to be called up on June 24. Complaints were rife against the decisions of the examining medical officers; and medical boards were substituted in May. A Ministry of Defence was created in Oct. 1916, which, under the authority of the Ministry of National Service, was to take over from the military to the civil authorities and the creation of the Ministry of National Service as a civil authority for recruiting. This new ministry took over all recruiting duties for the navy, army and air force on Nov. 1, 1917. A further Military Service Act was introduced in April 1918, rendering liable for military service all men between the ages of 18 and 51; but in actual practice the calling-up of the older men produced small results.

Under the authority of the War Office 2,631,313 men voluntarily enlisted between Aug. 4, 1914 and the end of Feb., 1916; and from March 1, 1914 to end of Oct., 1917, 2,790,581 men were called to the Colours; this gives a total of 4,421,894. Subsequently, under the authority of the Ministry of National Service, from Nov. 1917 to the Armistice (Nov. 11, 1918) 549,208 men were called to the Colours. After the Armistice enlistment again became voluntary, and the ministry enlisted 1,138 men into the regular army up to Jan. 15, 1919, when recruiting was retransferred to the War Office.

Higher Formations by Theatres of War.—The gradual expansion of the British armies in the various theatres, and variations in the strategic situation, led to changes in the organization of higher commands and to movements of the minor formations comprising them. It was not possible to deal here with the changes in organization of the higher commands, theatre by theatre.

France (and United Kingdom).—The first Expeditionary Force was organized as one army, sub-divided into 3 army corps. The I. and II. Army Corps and cavalry division took their place on the left of the French army in Aug. 1914, and fighting had commenced before the arrival of the 4th Div. and the III. Army Corps headquarters to which this division was allotted. These, however, took part in the operations from Le Cateau onwards, the 19th Inf. Bde. (composed of battalions originally allotted to the lines of communication) for the time being taking the place in the III. Army Corps of the 6th Div., which did not join the army in the field until the middle of September. The army was commanded by Gen. Sir Arthur Henry A. A. Currie, of the 2nd Div., by Lt.-Gen. Sir J. A. Murray as chief of the general staff, Lt.-Gen. Sir C. F. N. Macready as adjutant-general, Lt.-Gen. Sir W. R. Robertson as quartermaster-general, and Maj.-Gen. Sir F. S. Robb as inspector-general of the lines of communication. The I. Army Corps was commanded by Lt.-Gen. Sir D. Haig, and was composed of the 1st and 2nd Divisions. The II. Army Corps—originally commanded by Lt.-Gen. Sir J. M. Grierson, who died in France en route to the position of assembly—was subsequently commanded by Gen. Sir W. H. L. Simonds, and was composed of the 3rd and 5th Divisions. The III. Army Corps was commanded by Lt.-Gen. W. P. Pulteney, and was composed of the 1st, 2nd, 3rd and 4th Divisions. The cavalry division was commanded by Maj.-Gen. E. H. H. Allenby.

In Oct. 1914 the 7th Div. and the 3rd Cav. Div. landed at Ostend under the command of Maj.-Gen. Sir H. S. Rawlinson. In Nov. 1914 the 5th Div. had been expanded to a corps of three divisions under Lt.-Gen. Allenby. Two Indian cavalry divisions composed of British and Indian units arrived shortly afterwards.
The remainder of the army was organized as follows:—I. Army Corps, Gen. Sir C. H. H. Allenby (Pulteney), IV. Army Corps (Rawlinson), Indian Army Corps (Lt.-Gen. Sir J. Willcocks). There was shortly added the V. Army Corps (Gen. Sir H. C. O. Plumer). The Expeditionary Force had now attained dimensions which necessitated its further sub-division and the term “Army” was introduced on Dec. 26, 1914, after which the army corps were designated “Corps.” General Sir Douglas Haig was appointed to command the I. Army, and Gen. Sir H. H. Allenby was given command of the II. Army Corps. Gen. Sir C. C. Monro appointed the I. Army Corps, Lt.-Gen. Sir W. R. Robertson became chief of the general staff in France in Jan., 1915, and Lt.-Gen. R. C. M. Maxwell was appointed to command the II. British Army Corps in France, which became the II. British Army Corps in 1916, Lt.-Gen. G. H. Fowke became adjutant-general. The II. Army Corps was formed in July, 1915, and Gen. Sir C. C. Monro appointed to the command; he was succeeded by Gen. Sir E. H. H. Allenby, in Oct., on his appointment to the command-in-chief in the Dardanelles. The reorganization of the French armies was conducted by Gen. Sir H. C. O. Plumer, the II. Army Commander. At the end of the war, this army corps comprised G.H.Q. troops; Royal Air Force (T. M. Salmond), HQ. Corps and 9th Bde. (directly under G.H.Q.), with the 8th Div. (under General Sir H. Plumer) II. Army (Plumer) VIII., IX., XII., XV. Corps and 2nd Bde., R.A.F.; III. Army (Monro) and 4th Bde., R.A.F.; IV. Army (Rawlinson) IX., XIII. Australian Corps and 5th Bde., R.A.F.; V. Army (Birdwood) I., III., XI. Portuguese Corps and 10th Bde., R.A.F.

After the conclusion of the Armistice the bulk of the armies were demobilized or transferred home, the remainder forming, with young soldier battalions from home, the Rhine and the necesssary garrison troops for Belgium and the Rhineland.

**Egypt.**—In Jan., 1915, the garrison of Egypt had been enlarged by the addition of troops from England, India, Australia, and New Zealand to a total strength of 130,000, under the command of Gen. Sir H. S. Horne. In June 1917 Gen. E. H. H. Allenby was appointed commander-in-chief in Egypt and Palestine, and the British forces in Egypt were reorganized as follows:—Army Troops: Expeditionary Force consisting of the 10th and 11th Indian Divs. composed of British and Indian units. The 10th Div. (Sir E. A. Murray) was sent to Italy as was originally intended, Gen. Plumer returned to France in December. Gen. Sir M. Babington assumed command of the 11th Div. in March, and Gen. Sasoon succeeded Gen. Sir C. H. Maxwell. The Italian Army consisted of the British forces in Italy, the Italian Army, and the Italian Corps. The 11th Div. was placed under the orders of Lord Cavan for what remained of the campaign. The 48th Div. was temporarily attached to the 11th Corps.

wode, and the desert column under Maj.-Gen. Sir H. G. Chauvel. In the early part of 1918 further reorganization became necessary, and on Aug. 19, 1917, the corps was broken up and the formation of the Army was retaken by G.H.Q. troops: Desert Mounted Corps (Lt.-Gen. Sir H. G. Chauvel), 4th and 5th Cav. Divs., Australian and New Zealand Mounted Div., Australian Mounted Div.; XX. Army Corps (Lt.-Gen. Sir W. R. Marshall), 46th and 60th Divs.; XXXI. Army Corps (Lt.-Gen. Sir E. S. Bulfin), 3rd (Lahore), 7th (Meerut), 54th and 75th Divs.; Palestine line of communications; forces in Egypt—force troops (including Sollam District), Alex., and the Delta.

Salonica.—The Allied forces, in anticipation of the Greek nation joining the Entente Powers, commenced to assemble in this theatre of war in Oct. 1915, under the command of Gen. Sarrail. In the following year, in this first phase of operations (the attempted relief of Serbia, and the withdrawal to and the defence of the Salonika region), the British forces engaged were under the command of Lt.-Gen. Sir H. M. Simpson, and included the 5th, 7th, and 27th Divs. The 27th Div. was transferred to Egypt at the end of Oct., but returned to Salonika in Nov. 1915. These were followed by the 26th Div. from France in Jan. 1916. In April 1916 the British forces were organized as: Army Troops (including Royal Flying Corps and a mounted brigade); XII. Corps (Lt.-Gen.Sir H. F. M. Wilson), 22nd, 26th and 28th Divs.; XVI. Corps (Lt.-Gen. Sir G. Milne), 10th and 27th Divs.; garrison of the islands of Mudros, Imbroso, and the Thracian coast, the battle of Gallipoli and the retreat of the British forces in May 1916, and Lt.-Gen. Sir C. J. Briggs took command of the XVI. Corps. The 60th Div. was transferred to Salonika in Jan. 1917, at the end of the spring operations of that year, but proceeded to Egypt in June of the same year. In Aug. 1917 the force was further reduced by the withdrawal of the 10th Div. to Egypt. Other transfers and changes of organization did not affect the Salonika forces; but the line of communication remaining was of course diminished when the brigades, as in other theatres, were reduced from 4 to 3 battalions in the spring of 1918. These 4 divisions later formed the "Army of the Black Sea." The line of communication was further diminished by the course of desertion, and as the result of events and decisions on Middle Eastern policy. During 1917 and 1918 various British forces operated in the Caucasus (3rd Army Corps, the military administration of Com- panied Gen. Denikin's (afterwards Gen. Wrangel's) operations in South Russia in 1919-20.

Mesopotamia.—Early in Feb. 1915 an Indian Expeditionary Force "D" was detached from the 4th Army and placed under the command of Lt.-Gen. Sir A. A. Barrett (who was shortly succeeded by Gen. Sir J. E. Nixon). This force seized Basra as a base and advanced on Baghdad. The total strength of the force at this period was 6,717 British and 10,242 Indian combatants, 5,890 non-combatant and 11,000 animals, including camels and mules. In Jan. 1916 Lt.-Gen. Sir P. H. N. Lake succeeded to the command, and the 3rd Lahore and 7th Meeurut Divs. were transferred from Egypt. The 5th Div. was also transferred from Egypt to the command of Lt.-Gen. Sir A. A. Barrett, (who was shortly succeeded by Gen. Sir J. F. G. Gorringe. On Aug. 28, 1916 Lt.-Gen. Sir Stanley Maude was appointed commander-in-chief of the force. It was now organized as: base and light industries division; Bashi-Bazouk Mounted Corps, 15th Indian Div.; Tigris Corps (Lt.-Gen. A. S. Cobbe), comprising 6th Indian Cav. Bde., 3rd Lahore and 7th Meeurut Divs., and 13th and 14th Indian Divs. Shortly afterwards the Tigris Corps was reorganized as the I. Indian Corps (Cobbe), comprising 6th Indian Cav. Bde., 3rd Lahore and 7th Meeurut Divs.; and the III. Indian Corps (Lt.-Gen. Sir W. R. Marshall), comprising the 13th and 14th Indian Divs. On Nov. 18, 1917 Lt.-Gen. W. R. Marshall was appointed commander-in-chief owing to the death of Sir Stanley Maude. The 3rd Lahore and 7th Meeurut Divs. were transferred to Egypt in April and Jan., 1918 respectively. Various reinforcements had been added to the force from time to time, until by Nov. 1918 it presented an Indian cavalry div. (6th, 7th, 11th, and later 3rd Indian Cav. Bdes.); I. Indian Army Corps (Cobbe), 17th and 18th Indian Divs.; III. Indian Army Corps (Sir R. G. Egerton), 13th and 14th Indian Div.; and the 1st Indian Div. (Maj.-Gen. L. C. Dunseville), 36th and 96th Ind. Inf. Bdes.

North-West Frontier of India.—From 1914 to 1917 frequent risings took place on the N.W. frontier, followed by punitive expeditions. In many cases were despatched or two mixed brigades and sometimes more. Three divisions were maintained as war strength on the Frontier throughout the period of the war. One of these divisions had headquarters controlling headquarters or groups of columns formed substantially by their respective divisions, though the order of battle was modified as required. The 1918 operations in Persia and in the Caspian region were carried out very largely by force working under the orders of the 4th Quetta Div. of the Indian Army.

North Russia.—Operations in this theatre took the form, initially, of occupying Kela and various points along the Murman railway and adjacent regions in the spring and summer of 1918, in order to prevent the Germans and the Finns from doing so. The Allied forces were small, and were to form a nucleus for an army to be created from demobilized troops. These plans extended to Archangel and to the Archangel-Volokva railways by another force. This too, though larger than that on the Murman line (numbering some 25,000 organized troops), was chiefly ineffective. In the spring of 1919 it had been decided to evacuate both North Russian theatres of operations, and Gen. Lord Rawlinson was sent as commander-in-chief to coordinate the two operations of withdrawal. The evacuation was successfully completed on Sept. 27 for Archangel and on Oct. 2 for Murmansk.

Other Theatres.—It is unnecessary here to deal in detail with the organization of the British forces in other theatres of war. Under Divisions, East Africa, and similar headings, the facts are given elsewhere. Some idea of the variety and complexity of the tasks which British and British Dominion military organization had to perform in the British-occupied zones and the occupied and dependent territories included Cameroon, Togoland, German South-West Africa, Taung (China), South Russia, the Caucasus, North and South Persia, Aden, the Gulf of Oman, Baluchistan, Burma, Samoa, and New Guinea.

Statistics.—In Aug. 1914 the total strength of the British army, in all theatres of action, was as follows: regular army, officers 10,800, other ranks 236,632; army reserve, 145,347; special reserve, officers 2,557, other ranks 61,376; Channel Islands and militia, officers 176, other ranks 5,437; territorial for military purposes, officers 10,684, other ranks 14,100; naval force, officers 661, other ranks 1,417; Bermuda and Isle of Man volunteers, officers 18, other ranks 312—a total of 24,866 officers and 708,618 other ranks.

In Nov. 1918 the army figures showed a grand total of 193,102 officers and 4,755,242 other ranks (excluding 388,590 Indian troops). The expeditionary forces alone comprised 112,200 officers and 3,114,079 other ranks; among the officers were 93,608 British, 13,582 Colonial, 4,901 Indian native, and 217 Egyptian; and among the other ranks were 1,983,665, British, 291,018 Colonial, and 254,457 Indian native. In the United Kingdom there was a total of 10,684 officers, 14,107, British, and 48,112 of other ranks, 9,720 Colonial officers and 210,533 Colonial troops of other ranks. The remainder were in India and foreign garrisons and dependent ports.

The total casualties reported up to March 14 1920 comprised: killed (including died from wounds and other causes, but not including 101,000 among the "missing" now "presumed dead"), 42,348 officers and 724,500 other ranks; wounded, 97,968 officers and 1,993,681 other ranks; and "missing," 4,211 officers and 242,772 other ranks (of these 101,000 had been "presumed dead," others, 1,993,681, time of time, but are not included in the figures for "killed".)  

Demobilization.—Practically the whole man-power of the nation had been mobilized during the years of the World War. Demobilization was not therefore an exclusively military problem. It was as much an economic and industrial one; and the reestablishment of particular industries on a peace footing would depend on the order of priority of release observed. It is, indeed, impossible, in formulating a modern scheme of demobilization, to reconcile entirely the antipathetic claims of the individual and of the State; and the War Office Army Demobilization Committee, which was representative of civil as well as military interests—decided, after considering all phases of the problem, that in the national interest a soldier's entitlement to priority of release must depend on his civil occupation rather than on the nature and length of his service with the Colours (see DEMOBILIZATION AND RESISTMENT). The Committee went further. They decided that two particular classes of men—called "Demobilizers" and "Pivotal Men"—respectively must be released in advance even of the period of general demobilization. To the early release of "Demobilizers"—that is, the men actually required in putting through the demobilization scheme as a whole—should be added the Finns (see DEMOBILIZATION AND RESISTMENT). The Committee went further. They decided that two particular classes of men—called "Demobilizers" and "Pivotal Men"—respectively—must be released in advance even of the period of general demobilization. To the early release of "Demobilizers"—that is, the men actually required in putting through the demobilization scheme as a whole—should be added the Finns (see DEMOBILIZATION AND RESISTANCE). The Committee went further. They decided that two particular classes of men—called "Demobilizers" and "Pivotal Men"—respectively—must be released in advance even of the period of general demobilization. To the early release of "Demobilizers"—that is, the men actually required in putting through the demobilization scheme as a whole—should be added the Finns (see DEMOBILIZATION AND RESISTANCE).
tries, as agriculturalists and miners—met with much opposition. Many of the men of this class, of course, had been the subject of appeal after appeal to tribunals for exemption and had little military service to their credit. Why then, it was contended, should they be released before men who had served four and five years in the Army? "Pivotalism" indeed was called "a basis in war." But it should be remembered that the maximum number of "Pivotal Men" to be released was fixed at not more than 150,000 (a figure which included the "Demobilizers" as well) and that they were granted priority solely for the purpose of assisting in the reorganization of the various industries and thereby of increasing the capacity to provide employment for the less highly qualified men. On the other hand, it is true that some men of 19 and 20 years of age, with little or no technical experience, were certified as "Pivotal" by the Ministry of Labour and given early release, while some bona fide "Pivotal Men" were not released until long after the general demobilization period had begun.

As early as January 1915 the question of demobilization had been given consideration. It was not, however, until February 1917 that a draft scheme was drawn up. This scheme, applicable to troops serving in France only, was a mere outline, but formed the basis of the detailed "Regulations" finally adopted. It provided that men should be withdrawn individually from units (in an order of priority previously determined but depending in the main on individual industrial qualification) and formed into draft units, called "Dispersal Units," which would be sent to appropriate "Dispersal Stations" in the United Kingdom and there demobilized; each draft for a particular "Dispersal Station" being, so far as possible, composed of men whose homes were in the "Dispersal Area" (the United Kingdom being, for demobilization purposes, divided into 18 special areas called "Dispersal Areas") in which the "Dispersal Station" was situated. When, by this process of individual withdrawal of personnel, a unit had been reduced to a "cadre" strength—such strength depending upon the number of men that the Home Secretary, in bringing home the unit's vehicles, animals and regimental equipment—would be returned to the United Kingdom and disbanded or re-formed, as the case might be, and the remaining demobilizable personnel sent for dispersal.

The scheme did not receive War Cabinet approval until November 1917, but Cabinet sanction was taken for granted; and in March 1917 an Army Order was issued providing that the "Industrial Group" of each soldier, his particular trade or calling, and whether he was employed in peace-time industry, should be determined, together with his "Dispersal Group," and that the maximum rate at which dispersal could be carried out remained as before. Just so many men as were released under the new Army Order could have been released under the old rules. And that the demand for release was as acute as ever was proved by the fact that after the Armistice 25,905 were released at the War Office. After the issue of the Army Order the weekly numbers of letters released were rising, and the method of release and the manner of its administration continued to be on the same lines as before.

The agitation continued and the situation was verging on the critical. Difficulties with the soldiers occurred at Folkestone and elsewhere. Something had to be done to stem the flood of discontent. On January 29 1919 an Army Order was issued abolishing the principle of industrial priority and substituting that of release on grounds of age or length of service. The good effect of this order was instantaneous. Yet the new Army Order wrought no fundamental change. The principle of release by age and length of service had always been recognized and had been embodied in the original scheme. The machinery of dispersal was in no way altered; the transport problem was still present in awkward circumstances, in which dispersal could be carried out remained as before. Just so many men as were released under the new Army Order could have been released under the old rules. And that the demand for release was as acute as ever was proved by the fact that after the Armistice 25,905 were released at the War Office. After the issue of the Army Order the weekly numbers of letters released were rising, and the method of release and the manner of its administration continued to be on the same lines as before.

The total number of men (inclusive of Royal Air Force personnel) demobilized from November 11 1918 to September 29 1920—the date for which the last official Bulletin was issued—was 196,920 officers and 3,866,668 other ranks. (E. S. H. F.)

II.—THE FRENCH ARMY

Although the decree of Aug. 23 1793 brought into being the principle of the nation in arms, it was not until after the war of 1870-1 that the principle of personal service for all was established in practice (law of July 27 1872). Thenceforth no one could take the place of another. Inequalities in peace-time service, however, still existed, through the operation of the ballot and certain concessions allowed to men on account of family circumstances, or educational qualifications. In 1889 a second stage was reached. Military service in peace-time was reduced to three years, but many categories of citizens, e.g. students and supporters of families, would serve only six months. In the event every year every citizen between the ages of 20 to 45 would be called, as all having served would be able to participate in the first engagements.

By the law of March 21 1905, the inequalities in the duration of military service in peace-time disappeared. Henceforth in France military service was declared personal and equal for all in peace-time as in war. Service in peace-time, however, was reduced to two years. The reduction of the duration of service to two years, together with the decrease of the French birth-rate, placed the French army in peace-time in conspicuous inferiority by comparison with the German army on a peace footing; and in 1910 an increasing volume of opinion demanded a return to three years' service.

In 1913 the German danger was apparent to the great majority of the French people. After bitter and prolonged discussions,
personal and equal service for everybody for three years in times of peace was adopted (law of Aug. 7 1913). Thanks to this law, France, with a pop. of about 40 millions (39,601,590), was able to raise an effective force of 3,780,000 men in a period of 15 days (Aug. 1 to 15 1914) by the calling up of 2,887,000.

In 1914, the French army on a peace footing was increased to 823,253 men of whom 777,715 were metropolitan troops and 46,936 colonial. The metropolitan troops were thus classified:—775,081 hommes de troupe (of whom 13,486 were in Morocco), viz. 47,233 sous-officiers, 45,377 corporals, and 650,073 privates, and in addition 1,534 administrative employees. The colonial troops comprised 45,032 hommes de troupe (of whom 20,420 were in Morocco), viz. 4,756 sous-officiers, 3,600 corporals and 37,506 privates. Eighty-four non-commissioned officers were employed at the headquarters of the colonial army. The term hommes de troupe corresponds in France to that of "other ranks" in Great Britain, viz. all ranks exclusive of commissioned officers. The exclusion of officers accounts for the difference between 2,887,000 & 823,253 and the total of 3,780,000 shown as the strength on mobilization.

On Aug. 16 1914 to June 30 1915, a further 2,700,000 men were called up to the army. From the class 1899 to the class 1916 all men were called to the colours; this amounted to a recall of 6,444,000 men. The three years' law and the previous military laws had thus given France (1) a covering army which made her front inviolable, or at least which determined the Germans to seek to envelop a wing rather than attempt to break the front; (2) a peace army able either to absorb or to provide cadres for a considerable number of reservists and of men of the territorial army. The rapid influx of so great a number of men caused high hopes in France of a happy and rapid solution of the war, when it started in 1914. But as things turned out its only result was to enable her to await, without disaster, the coming into line of Italy on the one hand, and the formation of a great English army on the other.

In Aug. 1915, when the war had already lasted one year, it was realized in France that Lord Kitchener was right in anticipating a war of several years. He himself had undertaken to form a military organization for a duration of three years; and France, having already called up numerous classes of reservists and of young soldiers, now became less hasty in calling to the colours those who remained. Thus from Aug. 1 1914 to June 30 1915 there were mobilized 5,387,000 men, which brought the total up to 6,444,000 men; from July 1915 to Oct. 1 1915 there were mobilized only 1,449,000 men in small batches.

The enrolments made by France in the course of the war reached a total of 7,842,000 French and 475,000 N. African and colonial troops, making a grand total of 8,317,000 men.

In the course of the war losses—in killed, wounded, prisoners, deaths from sickness and sick—made the numbers vary of men mobilized in the army and outside it. The need of food supplies also made it necessary to send back a certain number of individuals and parties of agriculturists who were recalled to service from time to time and then again released to work on the land.

At the beginning of July 1915 there began the process of withdrawing from the front men capable of working in munition factories. Such men were no longer, strictly speaking, mobilized, but they remained "mobilizable," and were recalled to the front when there was no longer any fear of a shortage of munitions, or when the need of the front line became dominant, as when Clemenceau at the beginning of 1918 withdrew the young workers from the factories. The following table shows by categories variations of strength.

In 1914 a Frenchman belonging to the army had two chances of life and one of being killed; he had hardly any chance of remaining without a wound. In 1915, this man had six chances of living to one of being killed, while the chances of being or not being wounded were nearly equal (two to one and a half). It was during the year 1915 that the dangers were the least; on an average one had six times as great a chance as in 1914 of not being killed.

If one takes into account the combatants in each of the arms of which the French army was composed, one sees diminishing little by little, but in a very perceptible manner, the number of infantry and cavalry, while the strength of the engineers maintained itself without great change. But the combatant strength of the artillery and air service was augmented in number by two to one in the case of the artillery and by six to one in that of the air service.

The army evolved towards material power, the rifle lost ground to the machine-gun, but the machine-guns more and more took second place to the artillery. As for the air service, it grew to an extraordinary extent. If, taking a table of numbers, a mathematician were to establish a rising curve, he would come promptly to the conclusion that in a limited number of years there would be more men fighting in the air than on the ground. And if in fact, despite the mounting numbers of the artillery and of the air service, the infantry remained queen of battles, the queen's retinue was no longer one of men on horse-
back, but one of great masses of cannon and machine-guns moving by her side and over her head.

So far we have dealt with the strength: the examination of the losses is still more conclusive.

Despite the substantial number of losses, the French army continued to be formidable. The variations in the losses of the cavalry are practically without meaning, for the cavalry fought sometimes as infantry in the trenches, sometimes on foot, at other times on horseback. Still it should be noted that in 1914, as in 1918, when the cavalry had occasion to engage in open warfare, i.e. to work as mounted men, their losses were considerably increased. During the pursuit-battles of 1918 the losses were particularly heavy.

Whilst the strength of the artillery increased from May 1915 to Oct. 1918 in the ratio of four to six, the proportion of the losses rose in ratio eleven to twenty-seven. For the air service the strength increased in the ratio of 8 to 52, that is to say 1 to 6.5—the losses increased in the proportion of 260 to 1,905, i.e. 1 to 8. The queen of battles, magnificently escorted in 1918 by the gun and the aeroplane, suffered less than before; it was her holiness and her relative safety the greatest danger. She remained queen. It is of interest also to notice that the war of movement was more murderous than trench war. The year 1916 was for the French army the year of Verdun and the Somme, fantastic battles when artillery projectiles fell like rain in a storm. However, this battle of a year cost far less than the six months' battle in 1914, although the strengths engaged were practically the same. In 1918 the infantry lost 132,000 men out of a strength of 650,000 men; in 1916 the proportion was 220,000 out of a strength of 1,450,000. Strong souls were and always will be needed to lead them in the battle of open warfare; and the education of an army must be directed accordingly.

**Man-Power.** —The evolution of the French army from 1910 to 1914 would not be sufficiently indicated, nor would one understand the defeats from Aug. 18 to 24, 1914, followed by the victories of Sept. 5-12, if one were only to study a table of strengths. How could it happen, one might say, that even in 1915 and 1916 the French army had not been sufficiently strengthened? The reply is simple. The French army, swelled by reserve divisions attached to it, had during Aug. 22-23 a numerical equality with the troops of the German II. Army to whom they were opposed. In the Woëvre the II. Corps, Chickering's force, had passed by a series of offensives to it, was equivalent in strength to the opposing V. German Army. In many places in the great battle that took place from Millhausen to Maubeuge, German units triumphed easily over French units of the same strength. At the Marne the contrary happened.

To find the explanation of this curious paradox, it is sufficient to follow the evolution of the French army before the war, and to compare the age of the combatants who were fighting respectively in the two camps. To obtain the numbers sent to her armies France had to incorporate all the recruit classes from class 1889 (men born in 1869) to the 1916 class. The men of the classes 1889-1905 had done three years' service in 1914, or the same classes six months only. Recalled twice for a period of 28 days, and once for a period of 13 days, the men who had remained with the colours for a short time were not in Aug. 1914 sufficiently trained to be battle-worthy. That is why the French army, swollen by reserve divisions attached to it, had during Aug. 22-23 a numerical equality with the troops of the German II. Army to whom they were opposed. In the Woëvre the II. Corps, Chickering's force, had passed by a series of offensives to it, was equivalent in strength to the opposing V. German Army.

In France the "tertiary army" is formed of mobilization from reservists (officers and men) of the older classes. 1

1 In France the "tertiary army" is formed of mobilization from reservists (officers and men) of the older classes.
tion necessary in turning from the habits of peace to the trials of war is hard for any youth to bear. And that has been particularly true during the years of service with the colours has been affected by time. If this applies to the French it is equally true of the Germans. In the early days of the war, when, of equal ages, the French and German youths were on an equal footing; where the Germans were younger they won.

Now, in any case, the French population consisting of 40 million souls, and the German of 70 million in one mobilization class from Germany had seven million to France's four. But, further, it was especially in the 30 years prior to the war that the difference in the birth-rates made itself felt. One can say then without appreciating errors that the French, so-called to the colours gave nine to Germany and only four to France.

The army corps of the French covering force, in which 80% of the personnel consisted of the three youngest classes, had a mean age of 22 years. The corps of the younger and the reserve corps of the covering of the younger classes and half of reservists, had a mean age of 25-26 years. The reserve divisions had a mean age of 31-32 years. The army corps of the German active army had a mean age of no more than 22 years in the Covering Force, and 23-24 years in the interior, while the German reserve army corps had one of not more than 25-26 years. In brief, all the army corps of the Germans, whether active or reserve, were still under the influence of the lessons and training during their active military service, while the French reserve divisions had everything to relearn.

Therefore, if one is to compare the strengths present in the French army, it must not count the divisions of French army; it must not count the reserve reserve corps which followed which the active army corps, or only count them as of very small value. For battle purposes the reserve army must be considered together with the reserve of to have been in favour of the Germans. But the reserve divisions quickly recovered themselves; their acclimatization was rapid. Already at the battle of the Meuse there was notable progress; at the battle of the Somme they were led vigorously, they called forth the respect of the enemy.

In 1914 France was organized to place under arms the whole population capable of carrying arms. It had already been remarked that the figures of evolution towards the ideal of 1793 were slow. Even after Sedan, Gambetta was able only to call up men by categorys—first the unmarried, then married men without children. Only in 1905 did the law become obligatory, personal and general, and it was not until 1913 that the law was made in which all could be given by, with equally, a strong peace army which could absorb the number of reservists and cover the mobilization and concentration. It is to note the force, which was expected at 10 weeks, while on their road is that is to say, three weeks after the order of mobilization—the army corps of the Covering Force were complete, the army corps of the interior were only just ready, the divisions of the reserve were not up to the mark, and the units of the territorial army were still values. This espite of three weeks which the French army enjoyed arose from two causes: the resistance at Liège and the extension which the Germans gave to their enveloping manoeuvre. It may fairly be said that the reinforcements of the French Covering Force were much more than the value of the French fortresses, which caused the German staff to seek to gain the valley of the Oise by the right of the line of the Meuse. And the events which were the result of a slow, aggravate the effect of the delay inherent in this place of attack.

The evolution of the French army from 1910 to 1914 in respect of its strength, the reinforcement of the Covering Force and the preparation of the battle, thus save the effectiveness of a natural frontier which exposed her to the greatest difficulties, if not to actual defeat.

When the war of movement ended and trench warfare commenced, it was bitterly regretted that the factories had been emptied of all their mobilizable workers; the vice principles which had governed the evolution of the army towards universal, personal and equal service had been. It was deplored that these men had not been left at work in their workshops whilst the others went to fight. It may be that these reproaches were ill-founded. If the 559,000 men who on July 1 1917 were in factories had remained there in Aug. and Sep., perhaps the soldier would have been sufficient, or if in the arsenals, but perhaps also the French army might not have had need of them, because they would have been better by the numbers of the enemy.

It is not justifiable, then, to say that the evolution of the army between 1910 and 1914 was on wrong lines. It was because the German army gave so wide a sweep to their enveloping movement that space and time has been saved. When the French had never to the left wing the V. Army and a group of reserve divisions, and to get in touch with the English Army. This space and time Prussia had meant to refuse to France in 1871 in drawing the new frontier. To gain space and time between the objectives those who have to organize the defences of the mulitlateral frontier; it was the purpose, equally, of the troops of the Covering Force. To lose the allowance of space and time is to allow the French army to mobilize and concentrate the frontier was the constant preoccupation of the staff from 1875 up to the month of Aug. 1914.

The Covering Force.—It is not possible here to deal with the organization of the fortresses which gave a military frontier to France, deprived as she was of every natural barrier. We shall limit our review of this question only to the organization of a strong Covering Force. These operations determined the order of battle of the French army.

In the first place there was built up one formation to which alone it was assigned the occupation of a French 20th Corps to face Germany; the VI. Corps this was great unit. Alone, this army corps watched over the frontier in 1875. Next, Germany was invaded by the French, and the French army arms in order to keep the balance, had to augment the number of units of the VI. Corps. This, becoming too cumbersome, was divided into two—the VI. (headquarters Chalon) and the XX. (headquarters Nancy). The VI. Corps was extended to the N. of Belfort as far as the Upper Moselle. This was the position in 1910, when, since Germany showed herself not only more and more aggressive but also more and more strong; it was necessary to concentrate the force on the frontiers. After the Moselle, the means of gaining, if not space, at least the time necessary to put in position in a prearranged order of battle the great military forces which the French had acquired. The armies who had been the men whom the three years' law provided. When they were promised, a new order of battle was adopted. A new army corps, the XXI., was created, with the duty of providing the covering force of the armies of the interior, had its regional limits completely altered; the district adjoining Belgium (Givet to Thionville) was allotted to it, and one of its divisions increased to three brigades further the divisions of the British and British armies.

Each corps of the Covering Force became in a fashion a company of the German army. The XXI. Corps was the advanced guard of the V. Army, the advance guard of the VI. and the IV. The XXI. Corps became on Aug. 9 1914 the advanced guard of the V. Army. The I. Corps acted as an advanced guard to the V. Army, sent towards the Sambre, and on the other flanks, B. Corps, C. Corps, and the two corps of reserve of Gen. Pur, operating towards Mühlhausen. Behind this formidable system of the six corps of the Covering Force, the commander-in-chief under Plan 17 could put his armies in position. Immediately prior to the war, Gen. Joffre had improved in detail the system taken for mobilization and concentration in order to avoid as far as possible any loss of time; he sought to gain even hours, in the hope of being able to avoid the disadvantage of the enemy, by speeding up the intervening stages between the date of the opening of hostilities and the time at which the armies would be strategically concentrated.

In the first peace—The French army in peace-time consisted of 21 army corps and three divisions of colonial troops available for service on the frontiers. Of these 21 army corps, the arrival of the XIX. Corps, stationed in Algeria, in time for the first battles was counted as a victory, though problematic. In addition there were two divisions of cavalry. On mobilization the units of the active army were brought to their war strength by the influx of reservists; there was created on an average one division of reserve for an army corps.

In the Frontier battle, Gen. Joffre had under his command not only the 44 divisions of the active army at home but also three active divisions drawn from N. Africa and the Alps, and 25 reserve divisions, 12 divisional reserves, 42 cavalry divisions, 12 divisional cavalry, 12 divisional troops, and line-of-communication troops. Altogether there were 62,145 officers and 2,689,000 men—1,155,000 rifles, 25,000 carbines, 160,200 sabres, 2,158 machine-guns, 4,698 field guns, 389 heavy guns, 192 mountain guns, 200 aeroplanes and 18 balloons.

If in addition to the troops which Gen. Joffre was able to place in the battle of the frontiers, there are added the Belgian army of 6 infantry divisions and one cavalry division, the British infantry divisions which in the first place Field-Marshal French brought, with one and a half divisions of British cavalry, the conclusion is this—there was not the smallest doubt as to the proportions of the forces. When not to proportional numbers, but by various factors, amongst which, as already noted, the initial lack of proficiency of the French reserve divisions must be given a prior place.

The order of battle of the French army comprised five armies, allowing four armies to be placed side by side in the first line, and one army in reserve behind the centre and left centre. Each army had a principal battle front, the other British and the left near the Belgian frontier there had been assembled a cavalry corps. Reserve divisions were placed in the centre of the battle front, between the II. and III. Armies, to carry out the investment of the fortified regions east of the Meuse heights between Verdun and Toul as required. Other reserve divisions were entrusted, concurrently with certain active forces, with the defence of the line of the Moselle to the Meuse—Foy, Froidard. A "group" of reserve divisions was brought to the right rear, and a similar group to the left rear of the long line. Belfort, Épinal, Toul, Verdun, Maubeuge received their war garrisons. Lille was declared an "open town" by the Ministry of War. Lastly,
a group of territorial divisions under the command of Gen. d'Amade in the region W. of the Oise was dignified by the name of an army.

The single purpose of these armies was to execute different missions of these corps. Thus, for example, the IV. Army, which under Pau 17 (wherein this army was in reserve) had only 3 army corps, had orders to be stationed at Pau, Gers, and Pyrenees, which had been the objective of the offensive of reserve divisions. A temporary army was formed for the invasion of Alsace under Gen. Pau; this was broken up when Joffre observed how seriously the left flank of the Allies was compromised by the advance of the German forces. The Lorraine offensive was broken up in Woevre; it was broken up before even the neighbouring forces knew of its existence. A sixth army was organized near Maastricht; this was the army which, reconstituted at Paris, fought the battle of the Ourcq. There were 4 army corps stationed at the junction between the I and the IV. Army, was formed during the retreat and fought gloriously on the Marne. In the course of the war, armies were created, broken up, and reorganized as the events demanded. Thus there was formed at Salonika an Army of the East.

After the loss of the Meuse heights, which followed the loss of St. Mihiel, the commander of the III. Army was for a time brought under the authority of the commander of the I. Army. This was the origin of the creation of "Groups of Armies." These had the advantage of simplifying the task of the commander-in-chief, which had become heavier and heavier; but it was evident during the offensive of April 1917 that this part of the machinery was capable of bringing its movement to a standstill. Opinions formed on this subject seem unanimous in considering the army group a temporary formation, which could not be considered in itself as a permanent army. Armies were seeking the same objective while the commander-in-chief had too many other urgent occupations to act himself. In 1918 the army had three groups of armies, East, Centre, North. For the offensive of April 1918, the armies of the Centre Army were composed of 3 groups of armies designated "reserve" (G.A.R.) were formed. In the final advance of Sept.-Oct., 1918 a group of armies of Flanders was formed of Belgian, French and British troops under King Albert.

An Army Corps is composed of 2 to 4 divisions of the active army and corps troops and included especially one brigade of the reserve. But certain army corps in Aug., 1917, had 3 divisions, but in the Ardennes division, for the easier mobility and comparative rest. The number of divisions was extremely variable, as was also the allotment of artillery in a sector.

An infantry division, originally consisted of 2 brigades of infantry, a cavalry brigade and a regiment of artillery. In order to give greater mobility and to decrease the number of infantry in comparison to the number of guns, one regiment of cavalry was suppressed. The territorial division had not only in the regiment of infantry but also in the battalion. The cavalry division did not undergo any great change during the war, although in 1915 two sections of machine-guns were added. The proportion of cavalry was increased and while many regiments of cavalry were disembodied or broken up.

A cavalry corps was composed of a variable number of divisions of cavalry. On the left wing of the French army the general-in-chief composed, for example, from special cavalry regiments, 3 corps, 3 divisions. During the battle of the Meuse, the commander of the IV. Army created a cavalry corps from 2 divisions which had been attached to one of them. During the offensive of the Ardennes, a cavalry corps was also created for a short time. In fact, the cavalry corps did not exist as an organized formation; when two or more divisions of cavalry were placed under the same commander the group thus formed was often called a cavalry army. A division of cavalry had 3 brigades of cavalry and a group of batteries.

Many were the variations through which the order of battle passed in the course of the war. But it is of special interest to mention what the French army of 1917 and 1918 was at the end of the war; the numbers can be compared with those shown above.

In 1918 there were at the front: 88,486 officers and 2,486,000 men. The composition of the army of the period without cavalry, was: 9,820 officers; 94,000 carabiniers, 33,500 sabres, 19,149 heavy machine-guns, 46,800 light machine-guns (an arm which had not been employed in 1914), 936 guns of 37 mm., calibre, 1,672 Stokes mortars, 30 motor-mounted 37 mm. and 27 field-guns, 76 field-guns of 155 mm. (75 mm.), 7,100 heavy guns, 240 mountain guns, 2,275 guns of position and trench artillery, 5,379 aeroplanes (which for the programme of 1919 increased to 6,000), 77 balloons, and 2,385 (a little later 4,000) dirigibles. In 1914 the army had 19,000 vehicles; in 1918 there were 88,500.

Under the law of Dec. 23, 1912, the French infantry in peacetime consisted of 4 regiments which was assigned to each of the 24 infantry battalions, in which the Bn. companies each; 8 "fortress" regiments had 4 battalions, and one regiment stationed in Corsica had a variable number of battalions. There were 31 battalions of chasseurs-a-pied, of which 18 (6-corporal designation) had 3 companies, and 13 battalions (6-corporal company) also. Four regiments of Zouaves had a variable number of battalions (4 company). Twelve regiments of native tirailleurs were composed like the Zouave regiments, but with a depot company in addition. Further, there were 2 Foreign regiments, 5 battalions of African light infantry and a number of Sahara companies. These undertook the role of guard and mounted excellent cadres for the units dispatched to the front when they were the most frequently occasioned of non-commissioned officers and men who could receive the highest influence. In principle each active regiment of infantry formed a reserve regiment, which consisted of 145 regiments of varying composition according to the resources of the recruiting districts; it included 7 territorial battalions of Chasseurs and 7 colonial battalions of Zouaves. The infantry was armed with the Lebel rifle, model 1886-93. There was one machine-gun section for each battalion of infantry and Chasseurs. Owing to the swiftness with which the French Parliament granted the demands of the army, the all-army units were not provided with machine-guns at the outset of the war.

The cavalry was composed of 91 regiments, of which 10 were special cavalry. Each regiment had 5 squadrons in peace and 4 in war. However, the 6 Special regiments could be reconstituted. In principle each army corps had a regiment of cavalry, and each division of infantry had a squadron. The other regiments of cavalry formed 10 divisions of cavalry of 6 regiments each. The "Heavy Cavalry Division" was sometimes applied to those comprising 4 regiments of dragoons and 2 regiments of cuirassiers; that of "Mixed Division" to those composed of 2 regiments of cuirassiers, 2 regiments of dragoons and 2 of light cavalry; and that of "Light Division" to those of 4 regiments of dragoons and 2 of light cavalry. The cavalry was armed with the sabre, carbine, and, in certain cases, with the machine-guns. Each division of cavalry was allotted a group of horse artillery and a cavalry company.

The artillery comprised 62 regiments of field artillery, in 3 or 4 groups of 3 four-gun batteries and 5 autonomous groups in Algeria and Morocco, composed of 3 batteries each. There were also 336 medium howitzers, 135 batteries of heavy artillery, 22 batteries of mountain guns, 30 batteries of horse artillery, 75 batteries of foot artillery altogether 800 batteries on the whole. They were composed of 8 regiments, of which one was a railway and one a telegraph regiment. These regiments formed 26 battalions, varying from 3 to 7 companies.

Each division had 2 railroad companies and 3 aviation companies; and in addition to aeronautical sections and a transport company.

The colonial troops formed 16 regiments of colonial infantry, of which 12 were in France and 4 in the colonies. There were 5 independent battalions and 2 independent companies in the colonies; one regiment of Annam rifles, 4 regiments of Tonkin rifles, 4 regiments and 8 battalions of Senegal rifles, 3 regiments of Madagascar rifles. The colonial cavalry consisted of 2 squadrons of Senegal Sapeurs, one squadron of army of Congo and 1, and one squadron of Indo-China natives. The colonial artillery comprised 20 regiments of rifles, 36 batteries, of which 18 were field and 6 mountain; in the colonies were 4 regiments and a independent groups. Finally in Morocco there were 6 mixed regiments with 3 battalions, of which one was a colonial battalion and 2 were Senegal rifles.

The French army had 21 army corps, but the XIX. Corps (Algiers) was not in the War, brigades were also so organized as such. However, 2 African divisions were brought over and attached to the V. Army, so that the troops figured at the front.

The active divisions of the metropolitan army (including 19 corps) were increased from 4 of 3,000 men each, to 9 of 5,000 men. Two regiments of cavalry were added in 1917 the 16th Colonial, 30th and 76th Divisions. In Italy, in 1917-18, there were 6 divisions detached from the French front, of which 2 remained to the end of the war, being reorganized under the command of the French Expeditionary Corps, 6,600 to 7,500 men, attached to the 1st Italian Army, and employed at Cyprus (1916), and in Syria and Palestine; in the African campaigns; in North Russia, and elsewhere.

(V. L. E. C.)

III.-BELGIAN ARMY

In 1910 recruiting for the Belgian army was still regulated, under legislation of 1902, on a voluntary basis, completed by drawing by lot. The peace effective strength was 42,800 men, and the effective total of the field army on mobilization was fixed at 100,000 men.

By the statute of 1913 Parliament established the principle that the defence of the home country was an obligation charge on the family. Each family must furnish one son at least for military serv-
ice. This reform placed at the disposal of the army an annual contingent of about 33,000 men. This increased considerably the effective subject to recall on mobilization, and caused a considerable reorganization of the army. The reform was only the last among many that had been instituted from a desire of assuring during times of peace a direct liaison between the two principal arms—infantry and artillery. This was the result of the mobilization of 1914, which was from a regiment of infantry and a field of artillery.

On a war footing, under the reorganization now effected, there would be 6 army divisions and one cavalry division. This was the absolute number of the Belgian army as it existed partially in 1914. It provided for an effective strength of 335,000 men, of which 100,000 were fortresses. But this would not be reached before 1918, when the recruitment would have been completed in all classes and parts. As in 1914 the total 8 junior classes recallable to the colours did not provide more than a total of 117,000 men, it was found that the field army, while mobilizing so vast a cadre, yet possessed of a diminution of the effective strength. For at the outbreak of the campaign the infantry units did not count in soldiers but in cadres—or half only of their strength. In fact the war surprised the Belgian army in the midst of organization. (1) The order for heavy Maxim machine-guns had only been completed in part; a certain number of companies in the field army equipped with Hotchkiss machine-guns which were taken from the armament of the fortresses. Owing to the lack of a fixed regimental scale of transport, all machine-guns were carried in requisitioned transport and this paralyzed their use. (2) It was intended that the divisional artillery regiment would have a group of field guns and 2 groups of 9-5 in. howitzers. As a matter of fact it consisted in the end of only one group of howitzers; the artillery of the whole army was equipped only with 75-mm. guns. The adoption of a 15-cm. howitzer was still under consideration. (3) The number of cavalry regiments should have been increased from 8 to 10. Only 3 of these regiments were formed; the cavalry divisions possessed only 2 brigades instead of 3. (4) The Air Force possessed a single squadron of aeroplanes. The infantry division was to be armed with the Mauser rifle of 1889 type, firing an ordinary pointed bullet.

After the battle of the Yser the Belgian army consisted of only 32,000 rifles. This excessive reduction of effective caused the suppression of the Provisional Artillery. Each army division consisted of mixed regiments (one regiment of infantry and one group of artillery). The 3rd Div. alone had 3 mixed brigades. It was with this composition that the army spent the whole winter 1914-15. The excess of artillery was reduced by 2 groups of 8, while the reduction of this army was to the dispositions of the 27th and 28th Divs. (British) in the Ypres salient.

A few days after mobilization the Government had decreed the calling-up of the 24th class. This contingent, and voluntary enlistees at the outbreak of war, formed a recruiting reserve of 50,000 men, who were at first collected in the depots around Antwerp and later taken to the district of the Pas-de-Calais after the evacuation of that fortress.

In the spring of 1917 the army was reorganized in view of its participation in the general offensive projected by Gen. Nivelle. The number of machine-guns employed was considerably increased. Ignoring the type of weapons in such a way, but keeping the type of machine-guns in each division, companies of 6 machine-guns were raised for each battalion of infantry. The adoption of the French light machine-gun at the rate of 6, and later of 9, weapons per company, caused a reduction of the effective in the proportions of about 180 men. As a result it was possible to increase the regiment to 4 battalions of 1,000 men in a brigade of 2 regiments of 3 battalions each. This solution being formalized in an Commanding order and one company of machine-guns. Later, the acquisition of a certain number of howitzers permitted each division to possess some fairly heavy material, and created further a brigade of 3 regiments of heavy artillery. Hence the composition of an army division in 1917 was: headquarters; 3 brigades of infantry of 2 regiments of 3 battalions; one brigade of artillery; one regiment of engineers of 2 battalions; one light group of 2 squadrons of cavalry; and one company of machine-guns. Each army division consisted of about 19 battalions; 2 cavalry companies, 1 howitzer group, a small number of motorized machine-guns, and 7 camouflaged balloons.

Under the Imperial Russian Government, the Ministry of War, on its military side, included (a) the chief council of the general staff, which controlled all questions relating to the development of the armed forces of the empire and the use of them in the event of war, and (b) the general staff itself, which controlled the conditions of military service and the inner life of the army. The chief council of the general staff was only formed in 1905, after the Russo-Japanese War. This allocation of the more important questions to a special body, presided over by the chief of the general staff, was a measure highly important for ensuring the carrying-out of basic reforms and improvements. At first the head of the general staff was exempted from subordination to the War Ministry and reported directly to the Tsar on questions under its jurisdiction, but after 3 years the existence of 2 bodies reporting on military matters was found to be inconvenient, and the chief council of the general staff was again included in the composition of the War Ministry. In it there were gradually concentrated questions relating to the constitution of the army and the working-out of war plans. The first head of the Russian general staff was Gen. Palitsin, who occupied the position from 1903 to the end of 1908; he was subsequently succeeded by Gens. Sukhomlinov, Mishalavsky, Gergors, Jilinsky and Jenushkevitch; the last named was appointed only a few months before the outbreak of the World War. With the advent of war, the troops assigned for military operations were entirely removed from the control of the War Ministry; the control of them was organized according to a special "Order for the control of troops in the field in war time." This order was confirmed by the Tsar on July 16-29, 1914, i.e. only 3 days before the declaration of war on Russia on the part of Germany. The order mentioned fixed the organization of the high command and the system of command and organization of the troops assigned for military operations, as well as the duties, rights and sphere of jurisdiction of the commanders in the field.

The highest troop division in peace time in Russia was the corps. Though the corps often formed part of the military district, this unit had a rather territorial than an operative character, and its commanding personnel served only as the basis for forming the higher command of the army. This new organization was invented by General Nivelle, for the grouping of the corps in armies, and of armies in larger combinations, called "fronts." The whole of the troops, those
The supreme command of all the forces was, in the event of the Tsar not wishing to assume personally, entrusted to a supreme commander-in-chief, who had the right to order military activities according to his own independent judgment. No Government inordinary in the history of Russia, but in case of mutiny of the troops. The supreme commander-in-chief, the Tsar, had the right to give the supreme commander-in-chief orders, or to hold him to account. At the head of a "front" there was a commander-in-chief, the Tsar, or, in the absence of the supreme commander, the commander who also enjoyed very extensive responsibilities. The supreme commander-in-chief had to fix his attention mainly on the conduct of military operations. The question of the supply of his troops with all necessities, in the broadest sense of the word, was left to the care of the supply bodies of the War Ministry, who were entrusted with general requirements only. Besides the conduct of military operations, the supreme commander-in-chief retained the higher command in the exploitation of the net of railways in the theatre of military operations, a control which was highly important, in view of Russia's poverty in railways generally. The staff of the supreme commander-in-chief was very limited; it consisted of 45 officers, 10 civil servants and 2 men of medical rank.

The commander-in-chief of a "front" was a man who controlled not only the military operations of his front, but was likewise responsible for the supervision of all the requirements of the troops subordinated to him. To make it possible to carry out the second half of his duties there was subordinated to him a part of the theatre forming the theatre of military operations with all the materials in it. In this theatre the supreme commander-in-chief had to see to it that everything that could not be procured on the spot had to be ordered in good time, from the interior of the empire through the supply bodies by the Ministers. He had also to be concerned with the supply of a staff and a series of councils subordinated to the head of supply who carried out all the plans of the commander-in-chief relating to domestic administration. The territory composing the rear of the army, the front, formed one or more military districts, the commanders of which were subordinated to the commander-in-chief through the head of supply. Lastly, the headquarters of the commander of an army was regarded and organized as the executive organ of the supreme commander-in-chief.

The system created by these regulations did not suffer any material changes in the course of the first two years of the World War. It was only in 1916 that the personnel of the supreme commander-in-chief began to be augmented by the formation of a whole series of new departments for which no need was felt in the first two years of war.

The basic principle of the Russian military system was the regulation relating to military obligations, which fixed the terms of military service. To turn fully to account one of the main advantages of Russia over the other European Powers, the numerical superiority of her reserve manpower, the system of military out of the state was introduced. The council of the general staff elaborated in 1911-12 a new scheme of compulsory service, which was approved by the imperial Duma and the Senate. According to this, military obligation was extended over all males between the ages of 18 and 43, including a reserve of 150 million, the aim being to meet the demand of the Russian population (between the ages of 18 and 43) consisting of over 28 million. This was the reservoir on which Russia could depend for the replenishment of her army in time of war. It could have been drawn upon in the interest of classing up during the war in the order of their call-up and then using both male and female conscripts as the need might arise. The system worked to the advantage of the army in time of war, as well as by extending military obligations to the different races in the country and to men of over 43, but the latter method was difficult to carry out, owing to the conditions of Russian life.

The new organization of the army was completed in 1910. It brought many changes, but was not successful in fully realizing the scheme mentioned, as, in carrying out the fundamental part of the work, two grave limitations were set. These were the comprehensive arrangements for the mobilization of the reserve troops, and the introduction of the permanent system of "secret cadre".s. The principal reforms carried out in the infantry consisted in a considerable increase in the numerical composition of the field-infantry units and in the strengthening of the cadres of the first and second lines. The formal classification of the infantry being left with 4-battalion regiments and the field artillery with 8-gun batters. These defects in organization were rectified later on.

The mobilization plan was supplemented and modified, and the whole comprised a "secret cadre" of the army in 1910. Under this system, when the troops passed to a war footing, from each first-line unit there were taken a certain number of officers and men, who formed the cadre on which the second-line unit was based. This cadre was supplied with weapons, field artillery. The organization of the cavalry and horse artillery remained, on the whole, unchanged. Howitzers were introduced into the field-artillery organization, and a beginning was made with the formation of heavy artillery. In technical resources the army was sufficiently supplied, owing to the lack of credits and the difficulty of manufacturing the necessary materials in home factories.

The distribution of the Russian army was made as follows: Of infantry there were 70 field divisions (1st, 2nd, and 3rd Guard; 1st, 2nd, 3rd and the Circassian Grenadiers; 1st to 5th轻; 1st, 2nd, and 3rd Cossacks, Ist and 2nd Circassian; 1st to 5th Turkestan and Kuban-Plastun brigades; 16 light brigades of 4, and 2 light brigades of 3-battalion composition), and 37 artillery divisions (1st and 2nd Guard; 1st and 2nd Circassian; 1st Turkestan and Kuban Plastun; each composed of 4 (6-squadron or 6-sotnia) regiments, excepting the 1st Guard Div., which had 7 regiments; 8 independent brigades (Guard; 1st to 3rd Cossack; 4th Cossack), each having 2 or 3 regiments; and a few smaller units. In war time the number of cavalry units was not increased; the number of Cossack cavalry units was supplemented by the formation of Cossack units of the 2nd and 3rd class from reserve men. In each infantry division was included an artillery brigade (6-8 batteries); in every light brigade an independent battery (3 battalions). The field divisions had attached horse artillery regiments of two 6-gun batteries. All the troops mentioned, in peace-time, formed into 37 army corps (Guard; Grenadiers; XXV. Army; 1-III. Circassian; 1. and II. Turkestan and 1-V. Siberian). The composition of the cavalry division (24 divisions) and 37 artillery regiments; each consisting of 4 (17-24 batteries) or 6-sotni regiments, the latter being independent cavalry, by divisions. The army corps was supplied with corps cavalry, mostly of Cossack units of the second and third class. On the strength of every corps there was, besides the field division establishment, one moriah (howitzer) division of two 4-gun batteries and one sapper detachment. There were also several heavy-artillery units as well as pontoon battalions, railway, transport and air units, which were distributed in war time, according to a special plan, among the armies. The draft-finding and supply of artillery and engineers were formed only on mobilization by creating cadres from the corresponding field units. As for the cavalry cadres, draft-finding units were maintained in peace-time as reserve cavalry regiments and divisions.

All the troops indicated above were, in peace-time, evenly distributed over the territories of the empire, but were mostly concentrated on the frontiers, on the western frontier in particular. This system of distribution had been in existence from old times, owing to the lack of railways and a desire to protect the frontiers as much as possible. The system, however, greatly complicated matters, as the main sources for war expertise of the field divisions were to the centre of the empire, and therefore, with an order for mobilization, the necessity arose of carrying out a considerable movement of troops over a long distance. In order to simplify this important matter, a plan was developed, ensuring a quick supply of troops from the centre to the frontier if required, one could observe a withdrawal in the permanent quarters of the troops from the frontier regions nearer to the sources of supply. The following were the tactics: In 1910, when 7 infantry and 2 cavalry divisions, with 2 staffs of corps, were moved from the western frontiers to the interior of the empire. This withdrawal aroused alarm at the time in France, and suitable explanations had to be made.

The whole territory of the empire was, for military-administrative purposes, divided into military districts (22 in number), at the head of which was the commander of the troops of the district. The distribution of the corps in the military districts was as follows:

1. St. Petersburg M. District Guard, I, XVIII, XXII Corps
2. Vilna III, IV, XVII, XVI, XXII Corps
3. Warsaw VII, XIV, XXI, XV, XXII Corps
4. Kiev IX, X, XI, XII, XXI Corps
5. Odessa XVII, XXXI Corporation
6. Kazan I5th
7. Caucasus I. C. H. C., I. C.
8. Turkestan I. T. H.
9. Orenburg I. Siberia, Cossacks
10. Irkutsk I. Siberia
11. Pri-Amur I. Siberia

The local administration in Cossack districts was organized on a special basis and was responsible for the conduct of civil and military affairs on the Cossack territory. In the period of the war the Cossack territory included the whole of the districts of Cossack territory, including the whole of the districts of Cossack territory, including

Cossacks, the Cossack army was placed on a war footing in 1910 on the "mobilization plan of 1910." A new mobilization plan, revised in certain respects, and known as "mobilization plan No. 20," had been drawn up in 1913, but in July 1914 full effect had not yet been
given to it; this was found necessary to discard it and to carry out mobilization by the somewhat out-of-date plan of 1910.

As every war is usually preceded by at least for less lengthy period of preparation and organization, it was, in order to safeguard mobilization, a declaration was previously prepared, called the "period preparatory to war," during which each unit and command was required to overhaul and test its equipment and to carry out certain detailed exercises and manoeuvres. The result was that all ranks were kept on leave or on detachment. This was proclaimed on July 26, 1914.

There were in Russia in 1914 the following permanent fortresses or Redoubts: Kovno, Olszta, Osovet, Lonza, fortifications on the river Narev, Zegrz, Novogeorgievsk, Warsaw, Ivanogorod, Breest-Litovsk, Kars, Kurshe; (b) Maritime: Kronstadt, Vileb, Sveaborg, Libava, Ochakov, Sevastopol, Batum, Vladivostok, Nikolaevsk-on-Amur. Modern developments in military engineering had made all these fortresses very antiquated. The profiles of the fortifications were weak and could not withstand the power of the modern gun. In case of siege, the guns had to be put in the trenches and the artillery was exposed to the defects of such a fortification. The Russians had prepared fortresses that was the most varied and of extensively antiquated types and ammunition was limited. In a condition such as this, the fortresses could not be a support for manoeuvre in the field, nor for that matter for operations at sea; on the contrary, they themselves needed the support of a living force. They demanded considerable numbers for their garrisons, and so further weakened the army in the field; to every kilometre there were hardly above 7 carriages, while in other countries of Western Europe it was twice and three times as much.

Macadam roads were sufficiently frequent in the main frontier regions of the Russian army, but away from those regions common roads only were available. The front adjoining Austria-Hungary had no macadam roads at all.

The war with Japan had had to a great extent used up the military strength, and Russia possessed and the provision of new technical resources of war such as heavy artillery, means of communication, motor-cars, wire, machine-guns, air craft—involving the assignment of large credits, and the manufacture of new units which had to be spread over a number of years. Moreover, as industry in Russia was in a poor state of development orders had to be placed abroad and the execution of these was complicated by questions of final technical procedure. This state of things resulted in the army, at the beginning of the war, being poorly supplied both with technical resources and reserves of ammunition. In certain respects the latter were not up to the recognized pre-war standards, low as they were the old army's limit, material and ammunition, as the army had to be provided with new materiel and equipment only in the case of Russia. As 1915 passed, it was as well as possible to start new production and the army was provided with the needed materiel and equipment at the beginning of 1916.

It is not possible to follow in detail the development of the Russian army after the mobilization of 1914. The strength of the armies of the N.W., W., and S.W. fronts, at different periods, is given by Gen. von Falkenhayn as follows:

No information is available as to the total ration strength of the Russian armies at different periods of the war, nor of the combatant strength of the forces on the Caucasus-Persia front.

The contrast between Eastern and Western standards of armament may be illustrated by comparing the French artillery strength with those of Japan and Great Britain. The gun armament of the army in battle at the Strypa (Yastoviet) on June 6, 1916, both being deliberately prepared offensives against an entrenched front:—

[End of page]
Strengths were very low, so that the smaller units had barely enough troops to assure the performance of the ordinary everyday duties, let alone engage in a war. In Italy, these troops, joined by the territorial militia, were permanently employed in police duty, and units were often split up into small detachments; drafts had to be furnished for Libya. In the circumstances, it was easy to understand how complete and effective mobilization was impossible. Complete mobilization of the permanent military forces was out of the question for a great part of the army, the troops of the various arms being stationed in such a way that whole divisions had neither cavalry, artillery nor engineers in their districts.

In 1915, as well as in the previous year, the permanent army was composed of two classes of reservists, the first and the second. But in proportion to the numbers, the second class was much larger, and in the case of the reserves, growing up over the years, the first was inadequate.

The mobile and territorial militia units were intended to be formed at given centres, on mobilization, from reservists only. The number of these units and their character was to be decided according to requirements, by royal decree. The mobile militia was designed to operate with the permanent army, but to perform more modest duties than the permanent units. In order to facilitate its organization in case of need, it was decided in 1916 to maintain in each army corps, attached to every line regiment, Alpine battalions, an armoured field-artillery regiment, a permanent mobile militia nucleus, to fill up with reservists in case of war and so form the new units. But in the latter case, the personnel of these new units would be raised to a strength of at least 600 men, and in order to bring them up to this strength, could be brought into being at such low strength as to constitute a mere pretence. Mobile militia units were very rarely embodied for training in peace-time, so that, everything considered, it would have been necessary to improve their organization and, in case of need, to increase the personnel of the units for use on lines of communication or for duty at home, there was still less preparation; units were practically never embodied in peace-time.

Arms were deficient both in quality and quantity. The Italian army never had an excuse (except the field of finance), but the reserves and the output of the factories were not sufficient to meet the probable requirements of war. Machine-guns were almost entirely lacking. Only one regiments in the entire army was equipped with small arms, few rifles were followed by machine-guns, a rearmament of the armament system was envisaged, which was carried out after the Italian War, for the efficiency of the artillery had been found insufficient.

The principal mobilization states were Italian. The mobilization of the permanent army was carried out, but the reserve was not yet ready. A considerable part of the mountain artillery was also equipped with a quick-firing gun. The programme of 1910, providing for 40 batteries of heavy field artillery, had not been completed. Twenty-eight 4-gun batteries of 169-mm field howitzers were all heavy field artillery available. The siege train consisted only of a few big guns and 134 medium guns, generally of an obsolete pattern. The supply of ammunition was scanty. Mortar mortar was deficient.

The supply of uniforms, equipment, material for artillery and engineers, as well as for sanitary services, was lacking in quantity and quality. The mobilization of the army was carried out on a grand scale, but the quality of the equipment was lacking. The mobilization of the permanent army was carried out, but the reserve was not yet ready. A considerable part of the mountain artillery was also equipped with a quick-firing gun. The programme of 1910, providing for 40 batteries of heavy field artillery, had not been completed. Twenty-eight 4-gun batteries of 169-mm field howitzers were all heavy field artillery available. The siege train consisted only of a few big guns and 134 medium guns, generally of an obsolete pattern. The supply of ammunition was scanty. Mortar mortar was deficient.

The whole number of citizens liable to military service was divided, mainly according to age, between three organizations: permanent army, mobile militia, and territorial militia. The permanent army was composed of units existing on the peace basis. In peace-time it was composed of professional officers and non-commissioned officers, and of men of the first and second categories.

The force on the estimates for the financial year 1914-5 consisted of 14,000 officers and 275,000 men. The number of permanent officers was insufficient even for peace requirements. Reserve officers were taken in the reserve and were not required to meet the immediate needs of the mobilized army. They could only total the 56% of the number required, and the sanitary service, which was more than 50% short. Professional officers of the levy who had passed the examinations and who applied to serve as officers. They underwent regimental courses, and those taken total their service as officers, while the reserve officers together fell short by 17,000 of the number required for general mobilization. The greatest shortage was among the artillery officers, who could only total 56% of the number required, and the sanitary service, which was more than 50% short. Professional officers of the levy who had passed the examinations and who applied to serve as officers. They underwent regimental courses, and those taken total their service as officers, while the reserve officers together fell short by 17,000 of the number required for general mobilization. The greatest shortage was among the artillery officers, who could only total 56% of the number required, and the sanitary service, which was more than 50% short. The law passed in 1910 in the hope of securing an adequate supply had not had the result hoped for. Most of the few who had adopted the army as a career were employed on special service outside the units.
were formed, with this important innovation that, instead of incorporating the comparatively old reservists, they were formed of levy men and young reservists, viz., with the same elements as the permanent army. This measure practically meant the suppression of the reserve. The large army in Italy was due especially and mainly to the levy system, by which approximately one third of the military units were formed by men who, among other things, were 18 years old. It has already been mentioned that the levy system was not well adapted to the kind of warfare that was being conducted. The young levies were not yet trained and therefore could not be put into the active units, which were thereby greatly reduced, and in their place troops were formed on the one hand, home and abroad. In this way the most striking deficiencies of pre-war times were as far as possible made good.

But this was not all. From the very beginning of the neutrality period the Italian army was strengthened along four important lines. The army had been greatly reduced during the years of neutrality, but had been increased by the many reinforcements that were sent to the various services. But there were also reasons for recruiting to the army, inasmuch as the army had been reduced, and the losses in personnel during the war had already been great. In 1913, the army had consisted of 1,500,000 men, in 1915 of 1,500,000 men, and in 1916 of 1,500,000 men, and in 1917 of 1,500,000 men, and in 1918 of 1,500,000 men, and in 1919 of 1,500,000 men, and in 1920 of 1,500,000 men, and in 1921 of 1,500,000 men. The numbers of the army had therefore been greatly increased, and the army had been able to carry on the war with the forces that it had at its disposal.

Notwithstanding, the Italian army had been strengthened along four important lines. The army had been greatly reduced during the years of neutrality, but had been increased by the many reinforcements that were sent to the various services. But there were also reasons for recruiting to the army, inasmuch as the army had been reduced, and the losses in personnel during the war had already been great. In 1913, the army had consisted of 1,500,000 men, in 1915 of 1,500,000 men, and in 1916 of 1,500,000 men, and in 1917 of 1,500,000 men, and in 1918 of 1,500,000 men, and in 1919 of 1,500,000 men, and in 1920 of 1,500,000 men, and in 1921 of 1,500,000 men. The numbers of the army had therefore been greatly increased, and the army had been able to carry on the war with the forces that it had at its disposal.
1911 model had a carriage which when in position opened into two, allowing of important changes of target without moving the gun.

This was a great advantage in view of the broken nature of the ground on the Italian front. Guns were drawn by animals, but at the beginning of the war the great majority of guns and vehicles for motor carriages. The mountain artillery and mule batteries were both supplied with light dismountable guns carried on mules. At the beginning of the war the number of guns and animals was sufficient, and adequately equipped, were armed with the modern 65-mm. gun and employed in the Alpine districts, generally remaining in position; while the mule batteries, much less complex than the gun batteries, were used with success on the plains or in hilly country, accompanying the infantry. Gradually, however, these batteries were equipped with the 65-mm. gun and the difference between the two kinds of batteries disappeared. In 1914, a large number of the batteries were the same, and the total number of 149-mm. howitzers made it possible, at the end of 1917, to allot to each army corps a mixed group of 149 A howitzers and of 30 A 75-mm. guns. One battery of howitzers, plus one of the groups drawn by motor and some of the others were left at the disposal of the supreme command. Towards the end of the war a group of three batteries of 149-mm. howitzers was assigned to each division of the army. The field artillery, camouflaged, was well-supplied and the obsolete batteries were replaced. At the same time the batteries were supplied with motor tractors. From the beginning of 1917 a well-supplied park of tractors was formed. After Caporetto, when the army was in retreat, the old ordnance was destroyed, 900,000 mules were taken as prisoners, 2,450,000, of whom 1,250,000 had resumed service, 300,000 were under treatment and expected to recover, 570,000 were invalidated and permanently unfit for service. The severe losses were sustained in 1917. The other years followed the same order: 1917, 1918, 1919, 1920. These losses, given corresponds to 1.27% of Italy's total population in Jan. 1915 (36,000,000). Subsequent more accurate calculations proved that the actual losses had been underestimated. Senator Mortara in his I Prospettive economiche, published in 1911, quotes the following figures:

| Killed on the battlefield | 3,170 |
| Died in hospital of wounds | 5,000 |
| Died in hospital of sickness | 5,000 |
| Prisoners who died of wounds | 10,000 |
| Prisoners who died of sickness | 8,000 |

Total: 66,000

This gives a percentage of dead to population of 1.86.

If 1917 is added to the above total 25,000 released sick prisoners who died during the period of demobilization, and 52,000 who died of disease during the same period, the number of deaths rises to 651,000. Wounded and sick men and pensioners returning in 1921 were attended to, but the partial results already then known led to the belief that the first set of figures given was far inferior to the reality, and that even those given by Senator Mortara would have to be increased rather than diminished.

Demobilization.—On the cessation of hostilities the army began the reduction of its forces to something approaching pre-war strength. Demobilization could not be immediate, there were still large numbers of troops on the Armistice line and in foreign territory; of having many troops under arms in the country to repress the disorders likely to occur after such a war; of regulating the discharge of troops in accordance with means of transport available, taking into account also the probability of emigration on the part of some of the men discharged and the possibility of employment at home for others. It was also advisable to keep numerous soldiers in the rehabsited territories to employ them in the urgent work of reconstruction. These and other considerations imposed a gradual demobilization of men as well as of animals and material. Demobilization involved not only a reduction, but also a transfer of the army on lines different from those of 1914 and in accordance with the lessons of the war.

The older classes of reservists were discharged first. The men were granted a reimbursement policy of medical expenses in a sum of money and their fare to return to their residence in Italy or abroad. Officers were discharged after the men of their class. Medical officers especially were kept in the army to attend to the wounded and sick. By the end of June 1919, 14 classes had been discharged as follows:
classes 1874 to 1876 in Nov. 1878; classes 1877 to 1883 in Dec. 1878; classes 1885 and 1886 in March 1919; class 1887 in April 1919. The 1900 class—which was the last called up during the war and which had left in February—was discharged on May 2nd and called on again at the end of 1919 and the beginning of 1920. With the discharge of these classes, and with that of other special categories of the younger classes, the total number of the colours, which in Nov. 1900 exceeded 3,000,000, was reduced on July 1, 1919, to about 900,000, of whom 72,000 were in the colonies, 54,000 in Albania, 27,000 in Macedonia, 9,000 in Asia Minor, 7,500 in France, and 2,000 in the United States. The date of discharge of 225 generals and 76,000 other officers had been discharged.

During the latter part of 1916 nine other classes were discharged, as follows:—class 1888 at the end of June, class 1889 at the end of July, classes 1890 to 1892 at the end of Aug., classes 1893 and 1894, at the end of Sept., class 1895 at the end of Oct., class 1896 at the end of December. Immediately afterwards men belonging to the pre-war orders and the second category of classes 1897 to 1898 were discharged, so that at the beginning of 1920 the Italian army consisted only of men of the first category of 1897, 1898 and 1899 classes. At the same time 130,000 reserve officers out of the 156,000 in service at the time of the Armistice had been discharged. The principal reductions in the different units of the army up to the beginning of 1920 consisted of the breaking-up of 5 commands of army, 21 commands of army corps, 45 commands of infantry division, one command of cavalry division, 31 infantry brigades, 6 brigades of bersaglieri, 49 Alpine battalions, 12 squadrons of cavalry, 180 field batteries, 80 mountain batteries, 105 heavy field batteries, 600 siege batteries. All the men of the 1897, 1898 and 1899 classes were discharged in Feb. 1921, when only the 1900 and the 1901 classes (the latter had been called up in Nov. 1920) were with the colours. By this date the last men who had fought in the World War had left the army.

VI.—UNITED STATES

In 1911 the actual strength of the U.S. regular army was 4,888 officers and 70,250 men, of whom 56,733 officers and men were stationed in the United States. Deducting the coast artillery, there was left, in the United States, a mobile army of only 31,830 officers and men. This small force was distributed among 49 army posts in 24 states and territories with an average strength of 700 men to each post, only one post having a capacity for more than 2,000 men. The army was entirely too small for the duties required of it, and increasing inability to maintain, the separate units of which had no organization higher than the regiment. There was no opportunity for manoeuvres on a large scale, little opportunity for the joint training of the several arms, and no practical experience for the officers of the staff-work and leadership necessary to the handling of larger commands. A partial concentration of troops on the Mexican border in 1911 gave the U.S. army its first opportunity for a division manoeuvre.

Under the Act of 1911 the National Guard of the different states had been assimilated to the regular army in organization and discipline, and was receiving financial assistance from the Federal Government in the shape of equipment and pay for manoeuvres and the loan of officers from the regular army for training. In 1911 this force was in far better condition than it had been at the outbreak of the Spanish-American War (1898), but it was still locally organized, was made up of men whose military association and activity were merely an incident added by interest and preference to their ordinary civilian occupation, and was affected by traditions and associations based upon state rather than national service. In 1911 the reported strength of the National Guard was 117,986 officers and men, and an Act of Congress was passed, to take effect on the expiration of the Civilian Conservation Corps, which provided for the increased enlistment so as to provide 200 officers of the active list of the regular army for duty as instructors and inspectors of the organized militia and National Guard.

Reorganization of 1916.—Successive Secretaries of War had vainly urged upon Congress the necessity of a reorganization of the regular army on the basis of larger tactical units. In June 1916 there was finally approved the bill known as the National Defense Act. This provided for an increase of the regular army to a total not to exceed 11,450 officers and 175,000 troops of the line, including the Ordnance Department, 42,750 non-combatant troops and 2,750 trained staff officers; 2,650 assigned recruits, and 5,733 Philippine Scouts, in all about 235,000 officers and men. The number of regiments was to be increased to 65 of infantry, 25 of cavalry, 21 of field artillery, 7 of engineers, with an additional number of regiments of mortars to be carried out by July 1921 and five annual increments, but the President was authorized, in case of emergency, to put them into immediate effect. The general officers of the line were increased in number from 7 to 11 major generals and from 17 to 36 brigadier-generals to provide the necessary general officers for the contemplated expansion. The period of enlistment in the regular army was altered to 3 years with the colours and 4 in the reserve. The National Defense Act also provided for bringing under the control of the Regular Army a single national guard, the entire expenses of which were assumed by the Federal Government. It was estimated that this force would ultimately reach in peace-time a strength of 17,000 officers and 440,000 men. The bills all arms of the army, and added that the control of the Government it would constitute 16 divisions. The Act further authorized (a) an Officers’ Reserve Corps, to be selected, trained and commissioned in time of peace for use only, up to and including, five additional generals; (b) an Army War College, to train specialists for the technical departments of the army, to be recruited in time of peace for use in war only.

The act of March 1916 created the National Guard Bureau. Since 1904 the American army had possessed no general staff. Since the early history of the country there had been a commanding-general of the army and a system of semi-independent War Department bureaus, loosely coordinated either with each other or with the line of the army, and there had always existed uncertainty and dispute as to the respective functions and authority of the Secretary of War, the commanding-general and the bureaus. In Feb. 1903 a Congressional Act abolished the office of commanding-general and created a General Staff Corps, to be composed of 45 officers, with a chief-of-staff who, under the direction of the President and the Secretary of War, was charged with the supervision of all classes of officers and men in the armed forces of the United States.

In actual practice, however, the separate and combined jealousies of the long-established bureaus, and still more the initial lack of training and experience in the first officers detailed to the new staff corps, served as a barrier to effective action.

The National Defense Act of 1916 provided (6) that 57 to be reached, however, only in five annual increments, and with the proviso that not more than half of these officers should be "at any time stationed, or assigned to, or employed upon any duty in or near the District of Columbia." In connection with the army legislation of 1916 Congress created also a Council of National Defense, to consist of the Secretaries of War, Navy, Agriculture, the Interior, Labor, and Commerce, with an advisory commission of 7 specially qualified citizens; and to this Council was committed the task of studying and coordinating the military, industrial and commercial resources of the nation in connection with its defense. The disorders in Mexico since 1911 had made almost continually necessary the patrolling of the long international boundary by the bulk of the regular army. In March 1916 a raid into U.S. territory by Villa had led to the calling-out of the National Guard and its concentration along the border, while an expeditionary force of regular troops under Gen. Pershing was sent into Mexico. In Feb. 1916 the expeditionary force, in addition, had almost entirely returned to their respective states. The close of this emergency, almost coincident with the entry of the United States into the World War, left the regular army with a large personnel, and in the face of its men of the age of service and beyond, on terms of enlistment and left the National Guard in the throes of a combined demobilization and reorganization.

Reorganization of 1916.—In 1916 the strength of the regular army was 5,791 officers and 121,797 men, of the National Guard 3,199 officers and 76,713 men, a total of 207,500 officers and men. In addition there were 97,905 enlisted men of the National Guard who had not yet taken the oath of federalization. The General Staff Corps, though by this date composed of trained and competent officers, had a total strength of only 41 members, of whom, under the law, only 19 could be stationed in or near Washington. Soon after the declaration of war by the United States, April 6, 1917, the evident and acknowledged military unpreparedness of the United States led to tentative suggestions from the Allied Powers that such a state of things could not be tolerated, and after the establishment of the American Expeditionary Force in France, there was merged into the more experienced units of the Allied armies. But the Government in Washington considered that, in spite of popular enthusiasm, American sentiment would not tolerate any such absorption. According to the announcement of the Secretary of War, under-chief of the American Expeditionary Force specifically charged him, while cooperating in all ways with the Allied military authorities, to "preserve the identity of the U.S. force. It was further stated that he had been ordered by S. F. B. Morse, that the mission of the overseas force was to be an offensive one. These two conceptions, maintained throughout the war, governed all plans and activities of the United States army. It was immediately decided (a) to send overseas promptly a small but complete body of American troops, in the form of one tactical division to serve as a nucleus for the development of the American army, in order that some American troops might be put into the trenches at the earliest possible moment, and (b) to follow this by an expedition-
ary force of sufficient size, if the shipping situation permitted, to make American military participation an effective factor in the prosecution of the war. Act of March 17, 1917, Gen. Pershing, with a small staff, sailed for Europe and in June the 1st Div. regular army, 12,261 men, accompanied by 2,798 marines, was embarked.

Mobilization.—On May 18, 1917 the President signed and approved the Congressional Act known as the Selective Service Law. It provided that, in addition to the regular army and the National Guard, there be raised for the emergency a national army, by selective enrollment of men between the ages of 18 and 30, of which the President was empowered to summon two units of 500,000 men each at such time as he should deem wise. The same Act removed, for the period of the emergency only, all restrictions as to the numbers and location of officers of the general staff. On July 3 the President called into service the entire National Guard and 16 divisional camps were established for their concentration and training. The first registration under the Selective Service Law, May 5, 1917, was carried out in the main by the voluntary efforts of citizens and gave a total of 9,587,000 registrants. The actual drafting into service was delayed by the necessity of waiting for the construction of the 16 divisional cantonments planned for the national army, and by the lack of equipment and especially of woolen clothing. The first draft, Sept. 1917, inducted into military service 296,678 men, and up to Dec. 1, 1917 there had been drafted from this first registration 396,043 men. On Dec. 15 voluntary enlistments of men between 21 and 30 were discontinued. From that date also all registrants were arranged in five classes according to their importance to the war effort, and the first three classes were given special consideration.

The men thus placed in Class I, were first rendered liable for military service, and in the sequel the four "defereed" classes were never called upon. In May 1918 Congress provided that the quotas of the various states should be apportioned to the number of registrants in Class I, instead of according to population. The final total, registered, including those coming of age during the operation of the scheme, was upwards of 10,491,000. Of these there had been, on Nov. 11, 1918, inducted into military service by the draft 2,801,635, or about 25 per cent. In July 1918 it became evident that the then extended military programme would soon lead to the exhaustion of Class I. In order to prevent the industrial disturbance and economic hardships incidental to calls on the deferred classes, Congress provided for the registration of all males between the ages of 18 and 45, both inclusive, and made registrants liable to service in the Navy and the Marine Corps as well as in the army. This registration, held Sept. 12, 1918, yielded an additional total of 13,228,000 registrants, but owing to the close of the war these were never drawn upon. The following table shows, in round numbers, the recruiting from month to month:—

Replacements.—In April 1918 there were added to the 32 training-camps already functioning in the United States nine replacement camps of various arms. These were intended to supply the necessary replacements (British "drafts") for the overseas troops, calculated at from 10% to 25% a month, and to obviate the necessity of drawing upon divisions already organized and in training.

New Officers.—One of the most serious problems which confronted the Department of the Interior and the War Department was to provide a sufficient number of officers. To meet this need a first series of 16 officers' training-camps was opened on May 15, 1917. Officers previously commissioned in the Reserve Corps were required to attend and in addition to the 30 second and volunteer officers. In Aug. there were graduated from this first series 27,341 officers, a number sufficient to meet immediate needs. A second series was opened in Aug. 1917 and a third in Jan. 1918. The first two classes wereimsitively civilian and were in an experimental stage, without a military element, and because of the need for officers of all grades commissions were granted up to the grade of colonel. The third class drew 90% of its candidates from the enlisted ranks of the regular army and its graduates were commissioned as second lieutenants. These first three classes had supplied, to April 1918, a total of 57,307 new officers.

Transportation.—The War Department realized from the beginning the greatest latitude in the carrying-out of his mission, had very early established the general staff of the Expeditionary Force, selected a portion of the French railways for American use, which seemed best adapted to the basic organization of the American army. But the War Department in Washington was in this matter dependent upon Congressional legislation. As the war progressed the necessity to transport men and supplies to France made a condition of affairs which threatened to jeopardize the success of the military programme. Each bureau, absorbed in the sudden expansion of its personnel, and in its own preparations for the road and supply, considerably retarded the passage of reference in general to the requirements of other bureaus or services or of the army programme as a whole. It was not until May 1918 that it proved possible to effect a redistribution of the functions of already existing bureaus; (b) the creation of certain new agencies and services made necessary as the result of the development and experiences of the army overseas; (c) the reorganization of the general staff into five main divisions in such a manner as to enable it to perform its proper functions of an effective central controlling agency.

The American Expeditionary Force.—The original American Expeditionary Force had contemplated in a general way the placing in France by the end of 1918 of approximately 1,000,000 men. Between July and Oct., 1917, after consultation with the Allies and a study by Maj. Gen. Pershing of Allied armies, a definite programme was drawn up. In order that the services of the rear might keep pace with the arrival of the combat troops this plan was divided into six phases and contemplated the placing in France by July 1918 of 1,000,000 men organized into 5 corps of 6 divisions each (4 combat, 1 training, 1 replacement), with 2 regiments of cavalry, the necessary corps troops, army troops, service of supply troops, and replacements. It was decided that the American combat division should consist of 3 regiments of infantry (of 3,000 men each, with 3 battalions to a regiment and 4 companies of 250 men each to a battalion); one artillery regiment of 3 regiments, and machine-gun battalion; one engineer regiment; one trench-mortar battery; one signal battalion; wagon trains; and the headquarters staffs and military police. These with the medical and other units for each division made a total establishment of 28,000 officers and men, making a total of 500,000 American service troops. These strength was increased in the operation of the American army, which was conducted by the French in the early part of 1918 and was completed by the American forces in the later part of the year. The reorganization of the French divisional troops was then completed, and the American divisions were formed into a single army division of 6 divisions. The American army in France, however, was in addition organized into three corporations: the 1st, or American, to join the French army; the 2nd, or American, to join the French army; in the field; the 3rd, or American, to join the French army. The American army in France, however, was in addition organized into three corporations: the 1st, or American, to join the French army; the 2nd, or American, to join the French army; in the field; the 3rd, or American, to join the French army. The American army in France, however, was in addition organized into three corporations: the 1st, or American, to join the French army; the 2nd, or American, to join the French army; in the field; the 3rd, or American, to join the French army.

Demobilization.—The problem of demobilizing was simpler for the infantries than for other corps, for the army had not been undermined to the same extent. Moreover, since all units contained a fair proportion of men from all trades and commercial activities, it had already been decided to demobilize by lot, and a large proportion could be spared. A few priority exceptions were made in the case of coal-miners, railroad men, certain post-office employees, etc. Demobilization of emergency units still in the United States began immediately. The third division was made in the National Guard, where only a few thousand men were still serving under enlistment contracts entered into prior to 1917, and in the National Guard, where recruits and replacements had infiltrated every organization, with drafted men. As under these conditions rapid demobilization would have meant the disbanding of practically all organized military forces in the United States, authority was granted by Congress, in Feb. 1919, to reemploy some of the men who had been called into the regular National Guard. To insure the return of all men as speedily as possible to their former places in the economic life of the nation, the general plan provided for the transportation of each man, previous to discharge, to the demobilization camp in or near the state from which he had entered the service. For this purpose three former training-camps were utilized. On arrival in the United States, unless sick or wounded, the men were immediately distributed to their proper discharge camps. There each soldier, after a final physical examination and other routine processes, was discharged, paid and entitled for his home or place of entry. Men sick or still suffering from wounds or war diseases were not discharged unless otherwise provided for. The initial lack of American tonnage delayed for a time the return and discharge of the overseas troops, but between Nov. 11 1918 and June 30 1919 there were returned from France 606,074 men and officers, of whom number 85,759 were reported in American ships. The record for the month of June was 434,786 men, the greatest number shipped across in any one month. In Nov. 1919 there had been discharged, in all, 179,860 officers and 3,436,266 men. The discharge of men in the ranks was completed on April 1 1920. (A. L. C.)

VII.—BALKAN ARMIES

(1) Serbia.—In 1911 the Serbian army consisted of 5 infantry divisions each of 4 regiments, one cavalry division, and special formations of mountain and siege artillery. The army thus comprised 20 infantry regiments of 3 battalions each, 4 cavalry regiments of 4 squadrons each, 1 field artillery regiment of 4 batteries, 1 siege artillery regiment of 2 batteries, 2 light field batteries, 1 heavy field artillery regiment, 1 mountain怎样 (in round numbers.) 3rd line reserve, one Ersatz division of 1st line reservists approximating in composition to an active division. In addition the commander-in-chief had for his own disposal one cavalry division, one gun battalion, one field ambulance (2nd class), one medical service, one siege-artillery regiment, some railway and balloon troops. The total mobilized strength, representing the maximum effort of the country, was about 200,000 men.

The effect of the Balkan War the 5 divisions of the standing army were increased by another 5 (the Kossovo, Vardar, Manastir, Shtip, and Ibar divisions), all formed from the new territory acquired. The artillery regiments (other than those formed by field batteries) were increased, however, to the very short time of peace which elapsed between the close of the 2nd Balkan War (July 1913) and the outbreak of the World War, the reorganization which had been contemplated could only carried out after the war. On being mobilized at the end of July 1914, when Austria-Hungary declared war, the Serbian army totalled about 350,000 men, and it was organized, now for the first time, in four armies of three divisions each.

(2) Bulgaria.—In 1911 the Bulgarian army was organized in 9 infantry divisions of 4 regiments (formed into 3 army inspectorates, each inspectorate formed 3 armies), and 11 cavalry regiments. The army thus comprised, on a peace footing, 36 infantry regiments (each consisting of 2 battalions, one non-combatant company, and one machine-gun section), 11 cavalry regiments (each of 3 squadrons), 4 field artillery regiments (each of 4 batteries), 3 field howitzer batteries, 3 siege artillery groups, 3 pioneer battalions, a telegraph, pontoon, and railway battalion, one mechanical transport company, one cycle company, one machine shop, 46 heavy field artillery regiments, 16 frontier companies. The total strength of the army was 3,891 officers and 55,709 men. The army was raised on the compulsory draft system. Expenditure was 8,000,000 leva from his 20th to his 40th year. The classes were called up annually and a man normally served two years in the active army (or three in the case of the special arms), and then passed to the reserve until the closing date of the year of his 40th year.

The infantry were armed with the 8-mm. Mannlicher with a range of 2,100 metres. A few Russian Berdan rifles were to be found. Each man carried 150 rounds on his person. The cavalry had Mannlicher carbines, and were armed with the 7.65-mm. Mauser, the standard weapon of French pattern: the 7.5-mm. Schneider-Creuzot field gun, 10.5-cm. field howitzer (Schneider-Creuzot), and 75-mm. Schneider mountain gun, with a few 12-cm. and 15-cm. Krupp and Creuzot howitzers.

On mobilization each of the 9 peace infantry divisions split into 2. Each of the 4 companies of the 72 infantry battalions expanded into a battalion. The 11 cavalry regiments, reinforced by the police force, formed one cavalry division of 6 regiments, and the (infantry) divisional cavalry. An infantry division on a war footing thus consisted of 4 regiments of 4 battalions each; 24 machine gun sections, each of 6, one medical service, and the regular amount of field artillery; one howitzer battery; 2 engineer companies. The mobilized strength of the field army was about 350,000 men. In addition 72 regiments of machine guns, 2 regiments of observation balloons (and L. of C. duties. There were thus about 400,000 men under arms.

After the Balkan War the permanent strength of the Bulgarian army was slightly increased, proportionately to the increment of population. A 10th division was established, and a reserve train was raised, and the army on a peace footing numbered 85,000 men.

In Sept. 1915, 10 divisions of 24,000 men each were mobilized according to plan, but as the World War progressed other formations were added. In 1916 an 11th Macedonian division was added, mainly of Macedonians in the conquered territory of Serbia. Later a 12th division was raised, and towards the end of the war there were 14 divisions in the field. The system of forming peace divisions into two, which had been followed in the Balkan War, had been dropped, but a division formed 6 regiments, instead of 4. A Bulgarian division of full strength was thus 23 battalions—24,000 rifles, 24 machine guns, 24 batteries of field artillery, 2 batteries of siege artillery, 18 bombers, all under command of the Bulgarian general staff on Sept. 15 1918—two weeks before the Armistice—shows a grand total of 877,000 men of all ranks under arms.

(3) Greece.—In 1911 an Act was passed which provided for the reorganization of the Greek army. This reorganization contemplated 3 large divisions of infantry (27 battalions each), corresponding much more closely to army corps than divisions. These were divided into a heavy artillery regiment, and technical troops. At the outbreak of the Balkan War in 1912 the total number of units which took the field were: 44 battalions of infantry, 16 cavalry squadrons, 47 batteries of field artillery, 16 siege batteries, and 16 machine-gun companies. The heavy field artillery regiment (active) divisions, each consisting of: 3 regiments (of 3 battalions, and 3 machine-gun companies each), 2 battalions of machine-guns (rifles), one cavalry squadron, 9 batteries field artillery or mountain artillery, 2 mechanical workshops, 13 engineer companies, 6 field ambulance (4th class) divisions. In addition to these 4 active divisions there were also 3 or 4 reserve divisions, similarly constituted. The army thus mobilized had a combatant strength of about 120,000 and a ration
strength of about 185,000. The total number of men with the
colours at the end of the war was 210,000.

c. 229

caliber of 4.7 to 5.5 cm, or the French 11-mm. Gras rifle. The cavalry had lances, and carbines of the same pattern as the infantry rifle. The field and mountain artillery was all German. By the end of 1915, 63 Schneeberg-Dangelia ("screw gun"), The heavy artillery was all of old pattern.

At the conclusion of the Balkan War a thorough reorganization of the armies was undertaken. By the end of 1915, 37,000 men were taken for the field army, so that there remained for use as Ersatz troops 160,000 trained men in addition to about 150,000 not yet trained.

On Aug. 27, when Rumania declared war on Austria-Hungary, the mobilization and marching forward of the army had proceeded so far that the advance against Siebenbürgen immediately followed the declaration of war. Rumania put four armies in the field, one operating in the Dobrudja and three against Siebenbürgen. The field troops were formed into 33 infantry and 2 cavalry divisions. After the decisive victory in Dec. 1916 the reconstruction of the army was seen to be a pressing necessity, and this was effected under a French military mission. The work of reorganization carried out by the French mission led to a number of important results. When the I. Army was again at the front. In the battles fought between the end of July and the middle of Sept. 1917, the army possessed an actually greater battle strength than when it entered the war.

VIII.—The GERMAN ARMY

In the four years up to the outbreak of the World War, intensified progress was made in the German army along normal lines, but in Aug. 1914 there began and continued an astounding military effort which in many ways differed from that which the peace-time system had led observers to expect. To attempt to understand that effort, therefore, one must return to fundamentals. General Ludendorff, in his War Memories, in saying that each of the various component states produced good divisions and poor divisions, adds—"Württemberg and Baden had only good ones." In this judgment the Entente intelligence staffs, whose specialty was study of the opponent's quality, would concur. Yet in 1870 these two contingents had a very small share in victory, and in earlier times too, though figuring in many wars as components of this or that federal army, never won for themselves an outstanding reputation for high quality. On the contrary, these countries were the very home of the old German Gemäßlichkeit, and in the 18th century Burke quoted Württemberg as a model of a peaceably and constitutionally governed country.

Yet, in two cultural waves, so to say, contributed to make the German army what it was: first, the tide of Germanic civilization which spread from the upper Rhine and Danube countries N.E. over the mountains and into the great plain of the Slavs, and secondly, the tide of Prussian "objectivity" and efficiency which in the 19th century set in in the reverse direction, from N.E. to S.W. And it can be said without forcing the facts, that the military quality of Germany was fundamentally soundest at those two moments in history when, in 1813, the sense of civilization and nationality worked for the first time strongly upon the hard "East-Elbians," and when in 1914-5 the spirit of business and duty imposed by these East-Elbians upon the peaceful S.W. made their inborn nationalism an effective instead of an ineffectual thing.

The study of these currents is, of course, practically the same as the study of German history. But one thing may here be emphasized. No other basic hypothesis than that of continuing national characters can account for the fact that these two comfortable S. German states were awarded primacy in military quality by a Prussian commander-in-chief. Were it otherwise, the quality of the various contingents would simply have been measured by the length of the period during which their respective states had been subjected to the civil and military training of Prussia. Such a criterion has in fact been applied, but it proved false when in respect of the field army of the relatively small states, as Prussian military ideas and methods provided the skeleton on which this spirit was made flesh, and which fortified the flesh against weakness, an objective account of the German army of the war period must begin with a schematic presentation of that skeleton.

Higher Formations in Peace.—The growth of the Prussian-German military organization from 1815 to 1914 is shown by the accompanying Table A (The Roman numerals indicate the corps to which a division belonged at the time considered. When
the corps numeral is in brackets, the division is attached to that corps as a third division.

It must be premised that the corps numbers indicate territorial districts as well as military commands. The six "Brigade" districts of Prussia during the period of army limitation imposed by Napoleon became corps districts after 1815, and two others were added when for the first time Prussia acquired Rhine possessions adjacent to France. The annexations of 1866 produced three other Prussian corps and corps districts, and thereafter the course of evolution is sufficiently indicated in the table. After 1871, of course, all new districts were carved out of the existing ones. It will be seen from Table A that during the organization of 1912 there had been bitter controversy—the general staff demanding five new army corps and the Reichstag conceding only two—and no fewer than 17 supernumerary regiments (more than the infantry complement of two army corps) were left ungrouped after the 20th and 21st Corps had been formed. These 17 were a fifth brigade and an eleventh regiment in the Guard, fifth brigades in the frontier corps regions 5th, 6th, 7th, 9th, 14th, and ninth regiments in the 2nd, 15th, 18th and 21st Corps.

There were, therefore, in the active army of 1914, 50 divisions (two Guard, 1-42, and 1-6 Bavarian) and 17 supernumerary infantry regiments.

N.B.—Two Bavarian army corps (4 divs.), one Württemberg and one Baden division took part in the war of 1870-1 as allies of the N. German Confederation.

The Empire period the typical form of growth had been the creation of third divisions in certain corps (usually frontier corps) and which from time to time coalesced in corps possessing districts of their own. These third divisions themselves were the product of a gradual growth. Resources in men, and from time to time the favour of the Reichstag, allowed the formation, now here, now there, of regiments and brigades supernumerary to the standard corps establishment (2 divs. = 4 bdes. = 8 regts.). In each of the greater reorganizations these supernumeraries had been swept together to form new divisions. But over the last re-
With a growing population, and with the competition of the navy for available funds, it was inevitable that there should be this divergence between the theory and the practice of universal service. The *reductio ad absurdum* was reached when, with a population more numerous than that of France in the ratio of seven to four, and in a period of feverish war preparation throughout Europe, Germany was not able to maintain as many soldiers under arms as France. This was the case from 1913 onwards, and it was due primarily to the expenses of the competition in naval armaments. Within the army itself there was no remedy, short of reducing the term of service, and all political and military tradition and influences combined to make this impossible. It was for the court and militarists in Germany an article of faith that the "barrack-army" was the blind instrument of government to be used against external or internal foes. This theory presupposes a discipline like in kind to that of a professional army; the civic characters inseparable from a nation in arms, however highly trained, were obstacles to that discipline, and any move towards converting the army into a citizen force was anathema, even in the year in which the centenary of 1813 was celebrated in a fever of national pride. Yet in Germany, as

It will be noted that the Landwehr is exclusively a force of trained men, and Landsturm I. consists wholly of untrained men. The Ersatz reserve, originally intended to produce part-trained drafts for the active army—and always legally on that basis—was in practice a category into which the physically fittest of the men excused from training were put, the remainder going into (or rather staying in) Landsturm I.

Table C gives statistics for recruiting in 1911 and 1912 (the outbreak of war prevented those of 1913 from being published) showing the practical application of the system.

1 The retention of men in the reserve and other categories for an additional half-year was meant to provide for the event of mobilization between Oct. and March, in which months the youngest class with the colours was still too little trained to mobilize with the rest of the army. At a man's third appearance his case was bound to be disposed of definitely.

2 Of whom roughly half, each year, were of the 20-year-old class mustered for the first time.

3 By far the greater number in these categories had been put back twice.
calculation that men, equipment and officers were available, the professional soldier could not believe that the most rigidly solidery army of the Continent would put such formations into the front line when there had hardly been time even to establish military routine, let alone to revive the habit of march and manoeuvre in the men.

Yet so it was. Schleifen's ideas of mass and force, though watered down by his successor Moltke, were translated into practice. Two months later, an even more surprising move was made in the same direction—the employment of troops 75% of whom were entirely untrained at the outset.

After invading the N. German coast for some weeks the 9th Res. Corps followed these (17th and 18th Res. Divs.). In the W. also were the 33rd Res. Div. formed at Metz, and the 30th Res. Div. formed at Strassburg, and three momentarily independent Bavarian Res. Bdes. 2

Thus, in the W., the theatre of the first great decision, 735 battle divisions were gathered of which 293 were reserve formations, and in the E. (E. Prussia) six active and three reserve divisions were left to meet the attack of the Russian Vilna and Warsaw armies.

The 17 supernumerary infantry regiments also mentioned were absorbed in these reserve formations (with one exception) and the Instructional Battalion (afterwards famous as the "Lehr Regiment") was expanded to provide the 12th active unit of the Guard. Otherwise these formations were created entirely at the moment of mobilization. Their organization was similar to those of the active army, but for want of guns they were provided only with six batteries per division and had no heavy artillery of their own. In some reserve regiments machine-gun companies did not exist. In sum, and allowing for the active units incorporated, one-third of the first battle forces were reserve (though certainly not improvised) formations.

There were, however, yet other formations not so prepared in advance which found themselves fighting before the end of August. On general mobilization, the reserve, Landwehr, Ersatz reserve and trained men of Landsturm II., up to 43 years of age, had been called out. Landsturm I.—the pool of untrained men of all ages—was left alone, but volunteers presented themselves in enormous numbers. There were thus far more men than were required, the Guard Corps depots could accommodate, and the volunteers were for the moment only registered. Enough men remained in the trained categories and in the Ersatz reserve not only to fill the active reserve, but create (a) Landwehr and (b) so-called Ersatz formations, as well as units of Landsturm for guarding railways and other sensitive points and for the sedentary garrisons of forts. Landwehr.—Landwehr brigades were formed to carry out the secondary duties which it had been supposed, would fail to reserve divisions. The Ersatz, and to some extent the reserve formations, having absorbed part of the resources of Landwehr I., these brigades were constituted with the remainder and principally with Landwehr II., that is, trained men up to the age of 38. Each army corps district, according to the resources of the region and also according to its output of "Ersatz" formation, produced two or three Landwehr regiments of three battalions each, with infantry, artillery, sappers and engineers attached. In all, 99 regiments and some other units, making 314 battalions in all, mobilized in early Aug. 1914. Of these, 30 brigades were assigned to the W. to follow the various armies or to be employed as reserve. In the same way, the Landwehr Corps (3rd and 4th Landwehr Divs.), was constituted as a field formation at the outset, and others also were formed into divisions. In connexion with these brigades and those who were added into line, a new breadth was given to the relief field troops of the necessity of occupying territory and guarding communications, so in turn they were after a short time relieved by Landsturm battalions, formed all over the empire from what remained of Landsturm II. and from the trained men of Landsturm I. up to 42 years of age.

Ersatz.—The term "ersatz" (replacement or substitute) was confined in normal usage to the category of reserve units who were simply registered, not (as a rule) trained, and kept at call to fill gaps in the active army. It was, further, the official designation of the depot formations which were formed on mobilization to provide drafts for active, reserve or Landwehr partially or permanently in the Ersatz battalions at the moment of mobilization were such that, in addition to allocating drafts for the field units, it was possible to create new units on a large scale. The principle followed in the case of the territory applied which was already constituted or in which field formations were formed, was that of the Ersatz battalions of each regional district to form and equip two service companies. Thus each district was able to produce a battlegroup, and in the case of a brigade Ersatz battalion and the "B.E.B.s. (Battalion Ersatz Bataillons) which are the equivalent of other units, appeared in the field in the last days of Aug. 1914 as "Ersatz Divisions" (Gard, 4th, 8th, 10th, 19th and Bavarian). The battalions had an irregular organization: they consisted of two to four mixed brigades, each brigade having four or five battalions, four batteries, a half squadron of cavalry and an engineer unit 4.

In addition, the Ersatz battalions of a few reserve and Landwehr regiments, also constituted, and these reserve were grouped in two mixed brigades (Res. Ersatz Bdes.).

The six divisions cited above all took part in the western campaign for the first few days of battle. They were provided wholly by the Ersatz battalions of the II. and central corps regions. In the E. a different system was followed.

It has been mentioned that three active corps, one and a half reserve corps and about 17 Landwehr brigades had been assigned to the eastern theatre. But in the alarm created by the Russian advance on E. Prussia, an instant augmentation became necessary. The formation of B.E.Bs. 5 was not attempted in the I., XX. and other regions and provinces (Metz, Strasbourg), but in the other cases, took great risks in improving formations in the east. Not only Landwehr and Ersatz battalions but the most diverse units of all arms were thrown into line, and in some cases, parts of the cavalry and infantry were taken in and formed into separate battalions, and divisions, first as mobile fortress garrisons but soon as field troops. It was no doubt considered that racial passion would give such forces a military value as against the Russians that would compensate for their deficiencies of training equipment. These miscellaneous eastern formations constituted the Thorn, Breslau, Grudzen, Posen and Königsberg "Reserves" or Corps, of which the two last named were equivalent to two divisions each, the others to one each. The formation of the I. and XX. Corps divisions of the two divisions has already been mentioned. Further, one so-called "reserve" division, the (original) 25th, was created from the readiest elements of the Thorn reserve division. This division was thrown off before the Thorn reserve as such became fixed as a division. The five fortresses named in fact were so to say volcanoes from which in various puisances regiments, brigades, and divisions were successively drawn together.

By the end of Aug., therefore, the German forces in the field consisted of several categories—the active divisions of peacetime, the reserve divisions nearly equivalent to the active in

1 Staff was guard, but not troops.
2 Other formations called "Reserve" detailed later were so only in name.
3 No Guard Landwehr infantry regiments were formed.
4 Mobile Landwehr brigades were also formed and constituted divided brigades—in their case two regiments with troops of other arms attached.
5 An example, Runge's regiment of Griepenkerl's detachment, Thorn Corps, which in the winter of 1914-15 seems to have consisted of half a mobile Ersatz battalion from the XVII. Corps region, half a mobile Ersatz battalion from the I. region, the mobile Ersatz battalions of the I. and 10th Saxons and parts of three Landsturm battalions from Posen province and Alsace.
solidity of organization, the Ersatz and Landwehr divisions, improvised but composed wholly of trained men and organized according to scheme; and wholly improvised, divisions hurriedly put together from miscellaneous sources in the fortresses of the east. Further, there were a number of mixed Landwehr brigades, both in the W. and the E., in addition to those forming parts of divisions, and a large number of Landsturm units, serving wholly as garrison troops in the W. but not uncommonly incorporated in mobile Ersatz formations in the east.

The operating forces as apart from the fortress garrisons and the troops allotted to occupied territory and lines of communication were divided into eight armies, I.-VII. in France and Belgium (in numerical order from right to left), and VIII. in E. Prussia. The Silesian Landwehr Corps (under Woyrsch) formed a separate command operating with the Austro-Hungarian armies.

The command was exercised by the Kaiser nominally, by the chief of the general staff (Molitke, Falkenhayn, Hindenburg) actually. In addition to supervising the eastern front and controlling war policy, the great general staff in its war form (the "squadron who died," Oberleutnant of O.K.L.) directly commanded operations in France. From first to last no special commander-in-chief was appointed for the western front.

In the E. the VIII. Army grew into a great organization, comprising at one time in 1915 seven German armies, without counting Austrian armies included in its scope, or the German Southern Army which was outside it. This organization was under the commander-in-chief E. (Oberbefehlshaber ost or Oberost), under whose headquarter the armies were grouped in two or more groups of armies (Heeresgruppen). But in spite of his title, the commander-in-chief E. exercised no powers of command over the Austrian front. Not until much later indeed was there unity of command in any form. As in the case of the Entente armies in the W., combined operations had always to be arranged between the German commander-in-chief E., through the chief of the general staff, with the Austrian higher command. Crises due to differences of opinion between the three authorities concerned were naturally frequent, and only gradually, by providing more and more assistance by direct reinforcements, did the German command obtain an ascendency that was effective, and then it was the chief of the staff of the army and not the commander-in-chief E. who exercised control and exercised powers of command over the Austrian front.

In the W., there was a strong case for the formation of groups of armies from the outset. The expedient of placing one army under the orders of another was tried occasionally, with unsatisfactory results. Otherwise, the control of events in the Marne campaign was in the hands of a distant O.K.L. into whose business the eastern front generally thrust itself and which at one time (late Sept. 1914) seems to have had its hands. It was not until trench warfare had set in that groups of armies were formed in France. In sum, then, partly through events and partly from unwillingness to appoint a commander-in-chief in the only theatre in which German forces were employed exclusively, the officers of chief of-staff and of commander-in-chief E. came to be overloaded with a mass of very varied functions which ranged from advising on economic policy and negotiating with Turkish staff officers and Lithuanian clergymen to weighing the pros and cons of a division of operation. This was a considerable factor in the final defeat.

The strength in units of the three arms for both fronts and for the interior in Aug. 1914 may be taken, inclusive of Landsturm, as 1,700 battalions, 950 field and horse batteries, and 430-500 horse, and 40 field and 20 cavalry batteries.

Of these, approximately 982 battalions, 410 squadrons, and 820 field batteries of active, reserve and Ersatz formations, with,

1 Heer in German implies always the army as a whole, the "Heer."
2 Heeresgruppe is a major subdivision of the Heer, and consists of several Armeen (armies) or Armeegruppen (army-groups, i.e. groups of corps either are small or too temporary in character to be regularly constituted as "armies" with defined areas and lines of communication).
3 Finally, by allocating individual German battalions to Austrian divisions.

behind them, some 165 battalions and 28 squadrons and 30 field batteries of Landwehr, formed the western forces. To these should be added about 120 mobile batteries of heavy artillery (6-in. howitzers, 4-in. gun and upward). In order to arrive at a criterion of combatant strength it has become customary to use the infantry division as the unit, and to count unattached forces as equivalent to so many divisions, chiefly according to their infantry strength. It is calculated that there were in existence in the first weeks of the war 125 German divisions, or their equivalents in Landwehr and fortress brigades. Of these 77 constituted divisions and the Landwehr, etc., equivalent of 20 more were in the western theatre on Aug. 23 (the date of "high water" in the first phase), and 26 divisions or equivalents in the field and the fortresses (chiefly the latter) in the E., of which 13 at most could be considered as constituted divisions. In Sept. a naval division (shortly afterwards expanded to a corps) was formed and added to the forces in Belgium, for military duty and (later) for coast defence also.

Inclining engineers, communication troops, administrative troops and others of all categories, the total ration strength of the army immediately mobilized may be taken at about 5,000,000. The number of untrained men liable to service (including youths of 17-20) was about the same.

The New Formations of Sept. 1914—The organization of all the above forces was either existing or deliberately prepared for in peace, with the exception of the Ersatz formations, and even as regards these latter, the idea of creating and employing them dates back to Schlieffen's tenure of office. But, especially, all had the common characteristic that they consisted wholly of men trained with the colours in peace.

The next pulsation of the national effort, in the last days of Aug. 1914, was the creation of a series of reserve divisions in which 75% of the rank and file were wholly untrained. It has been noted that the Kriegsfreiwilligen, who presented themselves to the number of about a million, had merely been registered. As soon as the mobilization tide had receded and the depots were free, viz. about the middle of Aug., these men were called up, and formed, with a percentage of trained men (chiefly Landwehr II.), into new "Reserve" units—numbered in the case of the infantry regiments from 201 upwards. These units were assembled in training camps, officered by such retired and reserve officers as would be a constant of endurance, divisions and army corps, and within six to eight weeks of formation thrown into the furnace of battle at Ypres and Lodz.

There were 13 of these divisions (43-54 R.D. and 6th Bav. R.D.), 12 constituting the 6 corps 22 R.-27 R. They have been described by German writers as "the glory of the country and the shame of the general staff"—the glory of the country in that the flower of its young men composed them, and the shame of the general staff in that, with a universal-service system existing in law and in practice, it had been unable to devise a system of service that would absorb and train them. These were the "leaves" who advanced in masses, singing, under the rifle fire of the British Expeditionary Force at Ypres and of the Fusiliers Marins at Diznude, and who at Lodz, with the Guard Res. Corps, first broke into the Russian positions and then extricated themselves from the most extraordinary "pocket" recorded in the history of the war. The story of these divisions may be interpreted in several ways. It will suffice here to say that their effort was the culminating point of the attempt to win the war outright, and that with its failure to do so, the German nation, not less than the army authorities, began to realize that the war would be a prolonged conflict.

One more series of new divisions was created, however, before the policy of preparing for a war of endurance was applied to recruiting. The class of recruits who would normally have joined for training in Oct. 1914 were called up when the depots were clear of the first "new reserve" regiments. These (infantry regiments 249-273 R.) with the remainder of the Kriegsfreiwilligen, were, unlike the preceding divisions, held back for intensive training before being put in the field. They constituted the 735th-82nd Res. Divs. (38-41 R. Corps) and 8th Bav. Res. Div.,
and were not put into the field till the “winter battle of Masuria” in Feb. 1915.

These divisions (except the Bavarian) were constituted on a new organic basis—that of three infantry regiments under one brigade staff instead of four in two brigades, a form which, as will appear presently, came to be adopted throughout the whole army. In artillery strength they were however superior to all previous reserve formations. The original reserve divisions had only six 6-gun batteries, and the first new reserve divisions, hurriedly mobilized as they were, had nine 4-gun batteries. In these second new reserves, the number of batteries was increased to 12 (as in active formations, but with 4 guns in lieu of 6 per battery).

With the creation of these divisions expansion proper ceased. Until 1917 no further divisions were formed otherwise than by regrouping existing units, and the intake of recruits of successive classes was, with very few exceptions, used for maintenance only. The end of Jan. 1915, therefore, marks the close of the expansion period. At that date there were 147 infantry divisions, or equivalents of infantry divisions.

Regrouping had naturally as its object the better strategic and tactical utilization of these 147 divisions. The first step was to sort out the miscellaneous formations of Ersatz and Landwehr, especially in the east. Accordingly, the Posen, Thorn, etc., corps were recast, divorced from the fortresses from which they had already become separated, and constituted as the 83rd-8th Divisions. These were on the 4-regiment basis, and the regiments after reorganization took the numbers 350-354 and 375-381 (annexed as Landwehr units) comprised in these divisions retained their original designations.

The battalions of Ersatz on the W. front (the “B.E.Bs.”) were regimented chiefly with numbers between 357 and 371. On both western and eastern fronts the Landwehr brigades still unattached were used to form divisions, bringing the number of this category up to 19 (1-5,6th Bav., 7-18, 1st Bavarian).

The next step was a more important one. It had become clear, first of all, that the army corps, as a working unit, was not supple enough, and as early as Sept. 1914 the practice had set in, both with the Germans and with the French, of regarding the corps headquarters as an organ for the tactical and administrative management of any two or more divisions which might be assigned to it. This led in sedentary warfare to the corps becoming an area or sector command, and in open warfare or for the handling of battle reserves as a headquarters told off to carry out a particular mission. In either case, the inferiority of the German numbers in both theatres of war enforced a better arrangement of the corps commander’s forces than the $2 \times 2$ system gave. In the spring of 1915, therefore, two series of divisions, numbered 50-58 (even numbers), 101-107 and 111-123 odd numbers, 4th Guard and 10th and 11th Bav., were formed by taking a regiment each, and also one-quarter of the divisional artillery, from 50 or more existing active or reserve divisions. Thenceforward practically half the divisions of the army were on the new basis.

One other formation of the spring of 1915 must be mentioned. This was the Alpenkorps, a division formed for high mountain work when it became evident that Italy would enter the war. This corps d’élite served in every theatre, not only in mountainous country, and at the last moment of the war was dispatched from France to attempt to stop the Allied advance in Serbia. It was exclusively Bavarian in composition.

During the spring and summer of 1915, to ensure against accidents, the effectives of units in 3-regiment divisions were considerably increased, company strengths of over 300 being frequent. Later, however, the precaution being seen to be unnecessary, some new divisions were formed out of this surplus; these were the 183, 185, 187 and 192, originally called flying (i.e. non-sector)“brigades,” but from the outset practically equivalent to divisions of the new type.

Practically no further additions were made till the battle of the Somme and the intervention of Rumania created a new situation. The creation of the so-called 5th Ersatz Div. and the 25th and 47th Landwehr Divs. (all three mixed brigades reinforced to the status of new type divisions) hardly amounted to more than a change of name.

The total of divisions and “equivalents” (the latter always diminishing as formations were regularized) remained stationary at the figure of 172 from July 1915 to the end of May 1916. The reduction of strength of the army was 28,219 men on March 23, 1915, and on March 31, 1916, 6,767,144; and the losses had been as follows:—(8 months up to) March 31, 1915, 281,386 killed, 205,241 missing, 83,562 wounded, 13,400 died of disease, etc.; (12 months up to) March 31, 1916, 376,954 killed, 121,040 missing, 897,475 wounded, 29,840 died of disease, etc. The “definitive” losses—dead, missing, wounded discharged as unit—are difficult to establish; but if we take for wounded not returned to duty the figure of 20% (which is a high one), we arrive at a total of “definitive” losses of all kinds of about 1,780,000 for the whole period. To repair these losses, and to increase the ratio strength by some 1,750,000 men as well, the intake of recruits necessary would be about 2,500,000. These recruits were (a) the Kriegsfreiwilligen, (b) the class 1914, called up somewhat after the normal date, (c) the class 1915 called up before the normal date, and (d) the class 1916 called up before the normal year.

As early as the autumn of 1915, in fact, Germany had been compelled to anticipate the conscription, to bring youths of 19 as well as those of 20 to muster, and to shorten the period of training to the minimum.

General policy followed was to consider a class collectively as a means to be allotted to specific ends. Later in the war the practice was carried to the extent that even when called up, trained and ready, a class was under embargo and could not be sent into the front line until the chief-of-staff, in consultation with the Government, should issue an order removing the ban. What may be called routine losses and wastage were made good, as a rule by returned sick and wounded or other experienced men rather than by recruits.

Early in 1915, partly in order to have a reserve at hand, and partly in order to ensure an intensive training under realistic conditions, the system of “Field Recruit Depots” was gradually introduced. When these had been established, men spent only half or less than half of the abbreviated training period allowed in the Ersatz battalion at home and the remainder in the Field Recruit Depot a few miles behind the front. Eventually there was one depot per division, with an establishment (in 1917) of 1,350, of whom 900 were recruits under training and the rest training staff and returned wounded waiting allocation. Further, as pools to meet losses which could not be covered by the depots of the divisions affected, large training centres were created at Beverloo (the peace training centre of the Belgian army) and at Wünschendorf. The training camps in Germany were of course utilized for home training, and in them from time to time new batches of divisions were created and assembled. The period spent by the soldier in training varied considerably: sometimes it was as little as one month in the Ersatz battalion and two or three weeks in the Field Recruit Depot or at Beverloo; in less critical times it might be four to five months in all.

Hitherto, it will be noticed, little or no call had been made on the 5,000,000 men composing the untrained half of the male population of military age. This was because the maintenance of the country’s economic life was more necessary than ever as the blockade tightened its pressure. Nevertheless, a certain coming-out of agriculture and industries began in the winter of 1915-16. Further, a law was passed in 1916 for the reexamination of men who had been rejected by the annual muster commissions as permanently unfit.

From the summer of 1916 the situation of the German army became very critical. The costly offensive of Verdun had been followed by the Allied offensive on the Somme, the Russian break-through at LUTSK, the sixth Isonzo battle, and immediately thereafter Rumania’s declaration of war. For the first time since 1914 the Central Powers were face to face with a simultaneous and prolonged strain on all fronts.

Before describing the measures taken to deal with this crisis, it is convenient to review the changes which had taken place in the meantime in the constitution of the fighting units themselves.

---

1 The 108 and 109 were improvised during the eastern offensive of spring 1915.
The new type divisional organization has already been set forth, but within the infantry regiment itself there had been important changes, and there had grown up, besides, a great force of non-divisional troops, which in some cases a pool from which allocations were temporarily made to armies as required, and in others were sector troops permanently allotted to particular parts of the front irrespective of the divisions occupying them. By now, the process of moving divisional troops into reserve was thoroughly established, though Verdun was the first battle in which the relief process was reduced to an almost mechanical system.

The changes may best be dealt with by arms.

Artillery.—It has been noted above that in the great reorganization of the spring of 1915 the field artillery had been reconstituted on the basis of the 4-gun battery. The number of batteries therefore shows a large increase in this year, corresponding to the creation of new divisions. But in the main, the number of field guns and howitzers remained at the same level as in the spring of 1915. It was in the heavy and medium artillery (these were not differentiated in Germany) that expansion, as distinct from regrouping, occurred. The field guns were multiplied by various methods: old field guns of 9 cm. were brought out and employed as position guns on the less important parts of the front, pending the production of modern weapons; special batteries of the number of heavy battalions, "heavy artillery" actually in the field was increased from about 150 in Aug. 1914 to about 1,100 by the autumn of 1915 and 1,200 by the summer of 1916. The batteries received various designations, which will not be given here; substantially, they were grouped as required under "batteries," and when actually in line were under control of the divisional artillery command of the sector. This was initiated a principle of organization which presents a decided bellicosity: the泷's inclusion of field artillery also—that of dividing the artillery into a portion which belonged organically to divisions and moved in and out of line with them, and a portion which was under higher control; this portion was partly employed in the various sectors as a normal allocation, partly kept in reserve to bring up the normal artillery strength of this or that sector to battle standard, as required.

During the whole of the war period obtained a wider distribution or was evened with more authority than the assertion that Germany put into the field in 1914 an enormously superior force of machine-guns. The facts, however, were known throughout to the Allied intelligence staffs, and are, as regards 1914-5, in no way extraordinary.

At the outset, Germany had only just completed the equipment of the active infantry with two guns per 1,000 rifles—the same scale as that of the British and French and Russian armies. The only difference was that they were employed in batteries, regimentally, instead of by sections task-wise as on the side of the Entente, and in the doubtful event of a battle in the close-in open of the British and French side since German guns were used at all, they were used in mass. There were therefore, some 16 (on mobilization 32) fortress machine-gun detachments, and 13 horsed machine-guns; in addition, 4,000 machine-guns on special service (such as pioneers, for instance). On mobilization, the majority of the reserve regiments were also provided with machine-gun companies, but for the armament of the remainder and of Ersatz and Landwehr units the fortress machine-guns (Sept.-Oct. 1915) into the field at once. The first and second new reserves were sent into the field with one section of two guns per regiment. From all sources, the total of machine-guns in service at the end of 1914 was not more than 2,000, as against a peace establishment of 1,600.

But the Germans were the first to recognize the predominant role of the machine-gun in trench warfare. Manufacture was started on a scale commensurate with its importance, and in 1915 there were large additions. The regimental companies, where missing, were created, and more a number of "field sections" or "additional sections" were formed and attached to regiments as such as German, had, either in organic companies or in attached sections, a force of 9 to 12 guns, though it was not until after the middle of 1916 that the latter number was reached universal.

Meanwhile, a new type of machine-gun organization had come into existence, the "M.G. Sharpshooter Troops," each troop having six guns. These were selected from the "sections" of 1915, specially trained, and called "Sharpshooter Platoon (Abteilung)" and attached to divisions as required for battle. Their debut was at Verdun in March 1916. By that date the number of guns in service had increased to about 8,000, and by the end of 1916 this figure was doubled. At the period here considered, the light machine-gun, afterwards the primary armament of all German infantry, had hardly come into existence. Experiments were still made on the battle front side, but the Madsen gun and the "Musketenbataillone," but the results were not promising. The success of the French "Fusil mitrailleur" and the British Lewis gun, however, made action imperative, and towards the end of 1915, to save the time which would have been lost in trying to design, manufacture, and stock in a new manner a light machine-gun was lightened sufficiently for use as an infantry weapon. This was not issued on a large scale till the end of 1916.

Trench Mortars (Minenwerfer).—At the outset of the war, the trench mortar (adopted from the "Fontaine Fort Artillery") was a close combat weapon of siege warfare handled by sappers; in this rôle it figured at the sieges of Liége and Antwerp, where its bombardment was particularly heavy. It was, however, a weapon of trench warfare which brought it prominently to the front. As in other armies, the infantry felt the want of some short-range weapon which would enable them to curb fire to destroy and to harass the opposite trenches, and in which the power of trench-mortar fire was so great. The Germans had here a real advantage in that they already possessed experience of the design and manufacture of these weapons, and for a considerable period they had the upper hand in this kind of armament. The standard type was the 14, 17, medium, and light Minenwerfer which belonged to the pioneer arm, which were permanently assigned to divisions and allotted within the division as required. Other Minenwerfer units were grouped in battalions and constituted a G.H.Q. reserve. Later the light Minenwerfer sections were permanently assigned to regiments, the others continuing as divisional troops.

Infantry organization as such remained unaltered, though the establishment was reduced in 1916, in order to meet the demands for men which were created by machine-gun and Minenwerfer expansion. At the same time a process began which in the long run proved injurious to quality as well as quantity. This was the establishment of "Assault" or "Storm" battalions. These were created, in anticipation of the Verdun offensive, in the winter of 1915-6, and there was a successful attempt to allocate all assault battalions and companies raised at this period to the assault battalions. In the assault battalions, proper, all trench warfare weapons were combined within the unit infantry guns, trench mortars, machine-guns and light flamethrowers. The separation of this sort from the bulk of the infantry was recognized by privileges and distinctions of dress. The net result, however, was to deprive the infantry of a lever of first-class men, who in 1918 could no longer be spared from the ranks of their units. Towards the close of the war, therefore, the assault battalions were broken up one by one, and all assault units came to be regarded as schools of offensive tactics rather than as units of the army.

Pioneers.—Besides the Minenwerfer and chemical-warfare troops which had come into existence, other special services had been added to the pioneers, notably a large number of searchlight sections. Such searchlight technology was well developed, especially as in the British service, of the engineers. The proportion of the pioneers themselves (British "field companies E.R."") was also augmented and more than one of the pioneers' battalions was "Infantry Pioneer Companies" which were in reality infantry working parties detailed for particular pieces of constructional work, and retained as units till these were completed. From 1916, a large number of new Landsturm battalions were formed, as labour battalions.

The possibility of Rumanian intervention had been foreseen for some time, and in preparation for it four new divisions had been created by regroupings in the eastern theatre. These were the 195th, 197th, 199th and 200th; all these were principally composed of Jäger battalions assembled in regiments, and the last named, like the Alpenkorps, was specialized for mountain work. A little later the g31st, 92nd, 93rd Divs. were formed in Poland for quiet parts of the front. Several mixed Landwehr brigades were also expanded into Landwehr divisions for the same service. At the same time the 1917 class was called up gradually (May-Aug.), a specially long training of 15 months before the normal time, and the product of the March in the Hindenburg industry was brought under training at the same time.

These measures, however, were not sufficient. To meet the pressure on all fronts not only men were needed, but, still more, increased flexibility of manoeuvre, and it became essential, therefore, to create new battle-worthy divisions. These were obtained partly by regrouping, and partly—in the early months of 1917—by creating another batch of wholly new divisions. During the crisis itself, which extended from July 1 to Dec., and then, with a brief respite, from Feb. to May 1917, it was
impossible to carry out regrouping with the smooth regularity of March 1915; the measures taken, therefore, extend over the whole period. They were as follows: (a) The constitution of new divisions (201-204 and 12th Bav.) out of old units existing in various theatres and of "combinations" obtained in the lines of communication, the Ersatz battalions and other military establishments in Germany. The infantry regiments of these divisions numbered 401-416 and 26-28 Bavarian. (b) The regrouping of all old divisions still remaining on the 4-regiment basis as 3-regiment formations of the new standard type—i.e., the completion of the process which had been half carried out in March 1915. This yielded the divisions 205-226, the 5th Guard Div., the 3rd Marine Div., and the Bavarian divisions 14th, 16th, and 19th Reserve—in all 27 apart from some additional Landwehr divisions obtained in the same way. Certain divisions, which lost not one but two regiments in this regrouping process, were compensated by new regiments numbered 389-400, 417-441 and 477, these being formed by grouping experienced companies taken from existing regiments of every kind. Somewhat later, on the verge of the offensive of Caporetto, the Jäger battalions still available and unallotted were grouped in a "Jäger Division," the last high-quality formation created in the war. (c) The creation of a series of new divisions, in somewhat the same way as the old first and second new reserves, at training camps in Germany. The quality of these was, however, far below that of the new armies of 1914. Although 50% were returned wounded men and men drafted back from the fronts, the remainder were of the class 1918, called up nearly two years in advance. (d) The numbers of these divisions were 231-242 and 15th Bav. (regiments 442-476; and 30-32 Bay.). At the time of the creation of these, the old 8th Ersatz Div. took the number 245. The creation of a series of divisions for home defence and garrison duty, which in effect were only groupings of existing Landsturm (in some cases Landwehr) resources. Of these only the 251st, 252nd, and 253rd were actually formed as such. The Metz mobile reserve which had existed since Aug. 1914, was numbered into this series; later it was freed from all connexion with the fortress, and a new Metz mobile reserve was formed in the last months of the war.

These measures, in the ensemble, increased the number of divisions or "equivalents" (the last being by now very few) from 172 to 213 in Jan. 1917, and 223 in May 1917, the final total reached being 238 in Oct. 1917. The 1917 class, the combed men of March 1916, and the soldiers who could be claimed from back areas, by no means sufficed to cover the needs of these new formations, at the same time as they made good the losses of Verdun, the Somme, Rumania and Russia, not to mention Arras and the Aisne. Already in Aug. 1916 there began the examination muster of the 1918 class, and by mid-November it began to join for training, though not one of its members had reached the age of 19. By now, too, the effective value of a "class" had sunk considerably, because of the percentage which had to be rejected not only for immaturity but for malnutrition as well.

The ration strength of the army, taken on the same basis as the previous figures, had grown by March 31 1917 to 7,630,436, but the loss of 311,034 killed, 26,016 dead of disease, 192,386 missing and about 250,000 disabled (of 875,107 wounded), in all about 775,000, had compelled the recruiting authorities to find some 1,643,000 recruits in the 12 months. And it was precisely at this period (Oct. 1916) that, under the energetic pressure of Hindenburg and Ludendorff—who had succeeded Falkenhayn at the moment of the Rumanian crisis—a great munition production campaign was started in Germany, which necessitated the recall to the factories of a large number (125,000 men in the armies '16-'17) of mobilized workmen and a check to the process of combing-out. On the eve of the battle of the Somme, the strength of the German army in combattants only was 2,260,000 in the W. and 590,000 in the E., or (neglecting the small forces in the Balkans and Turkey) 2,850,000 on all fronts.

In spite of the fact that the line had held both in the W. and in the E., and that Rumania, with its material resources, had been conquered into the bargain, the outlook for 1917 was dark. The Russian Revolution came, with its enigmas; unrestricted submarine warfare was proclaimed with the foreseen result of bringing America into the war on the side of the Entente; and the British and French offensive was planned in a hope, almost amounting to certainty, that the defence would break down. Skillful defence, and sins of omission and commission on the side of the Entente, weathered this crisis for Germany, with a lower figure. (losses than those of 1916, 457,800 to 332,150.) Hindenburg and Ludendorff were able to collect such free reserves as allowed them to check the last Russian offensive, inflect two defeats which ended the war in the E., and to carry through the Caporetto offensive that so nearly ruined Italy.

This they were enabled to achieve—so far as the factors were under their own control—by using up the class of 1918, by creating as many manoeuvre units as possible, by employing every means that presented itself to stiffen the sinking moral of the war-weary army, and by new tactical methods, of which the most characteristic element was the light machine-gun. These guns were already in the spring of 1917 available on the scale of three per company. By the close of the year most companies had six, and during 1918 the issue of both light and heavy machine-guns for defence against low-flying aeroplanes was extended to batteries and to transport columns of every sort. Heavy machine-guns, too, had risen in number to one company of 10-12 guns per infantry battalion, besides those of the divisional "M.G. Sharpshooter detachment" which numbered 36.

The characteristic of the army of 1917-8 therefore became economy of man-power, through constant augmentation of machine-gun power, and the reduction of losses. In 1914 a 5th-battalion division possessed 24 machine-guns, in the winter of 1917-8 a 9-battalion division possessed 216 light and 142 heavy, or 358 in all. The rifle strength of the standard battle unit had been halved, and the machine-gun strength multiplied 15 times in about three and a half years, even without taking anti-aircraft machine-guns into account. The ratio of fire-power to men exposed had very nearly tripled.

At this point, when the stage was being set for the final act, it is desirable to summarize in tabular form the number and distribution of German divisions (and equivalents) during the first three years in which manoeuvre on interior lines was constant. Table D forms, rightly understood, a summary of the history of the World War, so far as Europe is concerned. Directly or indirectly, it reflects all its vicissitudes.

Amongst these divisions a certain classification in respect of quality had been set up. In 1914 Landwehr and Ersatz and new reserve formations had been differentiated from active and reserve and from each other in composition and rôle, but with the constant and, till 1917, somewhat haphazard replacements of casualties, differences based on provenance had disappeared. Instead, differences based on battle experience had come into force, and though largely accidental at the outset, they had become effective through the machinery of replacements. Divisions recognized as "shock-troops" (a legacy of the trench-warfare period) were dignified by the name of Grosskampfdivisionen in their offensive aspect and Eingreifdivisionen ("Intervention" or counter-attack divisions) on their defensive; and they received the pick of the recruits and returned wounded. The rest, formations fit to hold the line merely, were currently called "sector" divisions, and received, in the main, less battle-worthy elements in their drafts. A real, though admittedly undesirable, distinction was thus established. The Entente intelligence staff rated the 203 divisions of the western front with which it was concerned in 1918 thus: 61 "very good," 103 "average," 22 "poor."

The difference was not reflected in organization, except in the sense that "shock" divisions were the first to be equipped to any new scale that had been decided upon. Thus, such divisions were the first to receive their complement of six light machine-guns per company. In 1918 they received a fuller allowance of transport, and also, as part of their "organic" artillery, a group of medium guns (two batteries 15-cm. howitzers and one battery 10-cm. long guns) in addition to their field artillery.

</table>

Otherwise, the equipment and organization of all the divisions assembled in France in March 1918 was the same: three infantry regiments, each regiment with its three battalions, three machine-gun companies, and three light Minenwerfer detachments, the whole under an infantry brigade staff; one field artillery regiment of two groups guns and one group howitzers (in all nine batteries), which (with sector artillery or reinforcing artillery) was under the divisional artillery staff; (one M.G. Sharpshooter detachment of 36 M.G.); three heavy and medium Minenwerfer batteries which, a little later, were reformed, with the light M.W. units, as infantry regimental companies. In the case of attack divisions, a group of three batteries of medium artillery was included organically and up to 40 or 45 army batteries attached for the purposes of a particular battle. In one respect only was material preparation wanting. Tanks were not looked upon with favour, only a few units being constituted.

All cavalry divisions in the W. were dismounted and acting as infantry in quiet parts of the line. They were in process of reconstitution as infantry under the name of Schützen.
numerical superiority disappeared with the accelerated arrival of American divisions in France. By July the rifle strength of the Germans was 100,000 below that of the Allies. Two Austrian divisions, and converted cavalry divisions, which were brought into action during the summer, were hardly more than a drop in the bucket. Company strengths could no longer be maintained. More and more the army became an army of machine-gunners, practising the infiltration method in attack and the elastic method in defence, but in its growing disillusionment becoming less and less apt for either form. Since both demanded a high moral in the isolated squad which formed the fighting unit.

As early as May it was decided to break up certain formations and to use their personnel as drafts for others. This process was carried out on a large scale from the end of July; 73 divisions disappeared by the end of Aug., 10 more in Sept. and 3 more in the first week of Oct. The 1920 class, called up and trained, reached the field depots from Aug. onwards, but for political reasons sanction was refused for its employment in the front line. This was the last resource, for unless a winter's respite could be obtained, the most complete combing-out of home industries and agriculture—now in any case impossible owing to the political situation—would not have yielded a sufficient supply of trained combatants.

The sinking of moral in the army manifested itself in the "black day" of Aug. 8. During that month and Sept., in spite of the stout resistance of many formations, the sentiment of defeat spread. At the last a final effort of propaganda convinced the army that by fighting hard, and only so, it might obtain honourable terms of peace. But it was too late. The end had come in Germany.

With the evacuation of occupied territory and the march home to demobilization—in most cases self-demobilization—the history of the Prussian and German army system built up by Frederick the Great, Scharnhorst and Moltke, came to an end.

The losses in the concluding year, from April 1 1918 to March 31 1919, are stated at 303,973 killed, 48,753 died of disease, 334,802 missing, and 823,498 wounded, representing a "definite" loss of about 940,000.

In the whole war, the losses amounted to 1,531,048 killed, 155,013 died of disease, 991,346 missing, 4,211,469 wounded; or a total of 6,888,870 for recorded military casualties.

IX.—The Austro-Hungarian Army

Till a few years before the World War it could be said that no great state took so little care for its army as the Dual Monarchy. National differences and constant party conflict prevented anything more than the barest necessities of maintenance being provided for, and stagnation and even retrogression ruled in the army itself in consequence. This was especially true during the period 1903-6, in which the constitutional conflicts in Hungary focussed themselves principally upon the question of the Common Army and led to difficulties of which the consequences were serious indeed. There were, however, in the last few years two causes at work which led to important developments. The first of these was the eternal Balkan question, which on two occasions—the Annexation Crisis of the spring of 1909 and the Balkan War of 1912-3—brought Austria-Hungary to the verge of war. Each time Austria-Hungary was unprepared for war. But in the long-deferred modernization of the military system was, under the pressure of circumstances, taken in hand, at any rate so far as patching up the more obvious defects was concerned.

The greatest sins of omission in the past had been those affecting the artillery; the danger of war in the south-east led to these being repaired, at any rate so far as the limited means allocated allowed of it, and also to machine-guns being provided. The latter had been under experiment with cavalry and mounted troops since 1903, and it was not until 1908 that their employment became general.

The second important influence was that of the two-years'-service scheme introduced in July 1912. This was only brought into effect after a prolonged parliamentary conflict, for the Hun-
carried to a very high degree, but its application to practice was not perfect. The directing organs—General Staff, Intendance—were adequate and well trained.

In general it may be said that no army suffered from such unusual changes at the outbreak of the formation and development of a sound and uniform military spirit as the Austro-Hungarian. All the more remarkable, then, is its actual performance in the World War, a performance which, in view of the handicaps, must be regarded as unique in history and can only be explained by the existence of a sentiment of military virtue, rooted in age-long traditions, which carried the army through to the very end.

**Mobilization.**—In spite of the fairly evident attitude of Russia, it was hoped in Austria-Hungary that the crisis of 1914 would be confined to a war against Serbia and Montenegro. Three armies were formed in the south-east. But when on July 30 the first combats were taking place on the Drina and the strategic deployment was in full swing, Russia came on the scene. The mobilization, hitherto partial only, became general, and the bulk of the forces of the Dual Monarchy formed up in Galicia, nine corps preceding thither direct while three corps already engaged against the Serbs, or about to do so, were drawn off to the north. Mobilization and concentration, as such, were carried out without a hitch, and the transfer of the II. Army to the N. also produced no delays worth mentioning.

**Infantry during the War.**—The infantry, worthyly sustained its past, and fulfilled the role of "battle-carrier," which was lived up to by serving with the colours at the outbreak of war but of reservists, Landwehr men, Landsturm men of all kinds who far surpassed expectations. Apart from inconsiderable changes, the infantry organization remained unchanged. Much of the increase in strength of the infantry had, however, been augmented by the increase in the recruit contingent. New drill regulations had appeared in 1911, and new field regulations in 1912.

In Aug. 1914 the Common Army included 102 infantry regts., 4 Bosn-Herzegovinian regts., 4 Tirolese Kaiserjäger regts. (all at 4 company-battalions), also 29 Feldjäger regts., one Bosn.-Herzegovinian, and 6 former companies in Bosnia and Herzegovina. The first reinforcement to replace casualties was provided for by 28 "march" regts., which followed the army into the field. The Austrian Landwehr had 37 inf. and 3 Tirolese Landsturms, and the Honved, 32 inf. regts.—all these being on a 3-battalion footing. The Austrian Landwehr possessed no "march" regts., the Honved on the contrary had 16. On the outbreak of war, of the 1st and 2nd bns. of the Landsturm there were formed 38 Austrian and 32 Hungarian Landsturm regts., as well as many independent Landsturm units, the number of which was temporarily augmented later when the Landsturm age limit was raised from 18 to 26 years.

Battalion strength was about 1,000 rifles, except in march battalions, which varied from 800 to 1,000, and in Landsturm battalions which rarely exceeded 800.

The equipment provided for in the war by sending up monthly one march battalion per regiment. Thus, in the course of the war, 48 march battalions were sent into the field for each infantry regiment. Training of machine gun detachments was given to the Austrian Landwehr were organized as mountain troops. Independent Jäger battalions were organized like infantry battalions, and had "march companies" as their reinforcement organ. Machine-gun detachments had been in process of formation for some years, and by 1913 all infantry battalions (and cavalry divisions) had them. The detachment was of 2 guns in the case of the infantry, 4 in those of the cavalry. In 1915 Landsturm machine-gun detachments were gradually formed for certain Landsturm battalions. In 1916 the number of guns in a detachment was doubled, in 1917 trebled.

The last year also saw the introduction of the hand-machine gun (light machine gun) forming a Gug of four Schwarzme (squads), each Schwarzme having 2 guns.

The introduction of new methods and weapons in the war, of course, did not end the four years of war, the dwarfed helmet and the gas mask being already comparatively well known. As a matter of course, the equipment of the war of 1914-1918 was not developed by evolution, but by a single leap. The equipment of the war of 1914-1918 was essentially a war of issued 26 posts and 52 km. of cable, the second 6 posts and 12 km. of cable. A further technical development was the introduction of the 37-mm. infantry gun.

Numerically, the organization of the infantry remained unchanged till the middle of 1917. In the second half of that year three Fedj-Jäger regts., the 383rd, the 384th, and the 392nd Regts. were formed, and also a number of fortress battalions for service in the Bosnio-Herzegovinian fort. The last name, however, were independent infantry divisions, the 92nd-107th infantry regts., and some combined "half-regiments" were created from various sources.

The introduction of all these units was more or less in the nature of a temporary expedient, necessitated by the necessity of forming an ever-growing front. It was evidently desirable to systematize the process of expansion, and therefore in Oct. 1917 a complete reorganization of the infantry was undertaken, broken in half by the necessity of forming the 1917 regiments of the infantry division into itself. All regiments were now uniformly organized on a three-battalion footing, and from the fourth battalions available and the four newest Bosn.-Herz. Jäger battalions, the new three-battalions regiments were created. At the beginning of 1918, therefore, there were 138 infantry, 4 Tirolese Kaiserjäger, and 8 Bosn.-Herz. regts., each of three battalions. In May 1918 a 139th regt. was added. The number of Feldjäger battalions, the (four) Bosn.-Herz. Jäger battalions and the front Jäger battalions remained the same.

In the Austrian Landwehr there was no change in numbers, but in March 1917 a regiment was formed in the Bosn.-Herzegovina, the Tirolese Landesjäger became Kaiserschützen, and the two Austrian regiments, 4th and 27th, formed as mounted troops, were renamed 1st and 2nd mountain regiments. The Hungarian Landwehr (in military style) the 1st and 2nd mountain battalions. In view of the course of the war 17 new regiments, numbered 300-316. At the end of the war the Landsturm formations in existence were still in the number of 15 regiments, about 10 independent battalions, 4 Tirolese battalions, and in Hungary 8 regiments, 16 independent battalions. Lastly, there were 91 Austrian and 65 Hungarian Landsturm line-of-communication battalions.

**Infantry Organizations.**—Patriots (squads) of picked men trained to grenade work and employed for special enterprises were already in existence in the spring of 1916, especially on the Isonzo front. These were formed in the latter part of 1917 by storm troops proper, and at the beginning of the year of the Austrian army. The Austrian Landwehr was formed a storm battalion and each cavalry division headquarters and each independent infantry brigade a corresponding unit, all these being formed from the storm troops of regiments, brigades, etc.

**High Mountains and Alpine Fighting.**—Cyclist units were formed for the fighting in the more difficult Alpine work. These numbered 20 and 13 respectively at the end of the war. Cyclist units existed even before the war (Jan. 1912), four companies from certain Jäger battalions being assembled as a unit. This unit did very well, and, in the war cyclist units were created in the Hungarian Honved, in both Landsturms (and in the Navy). Early in 1918 the Honved, however, formed a special battalion for high mountains and Alpine fighting. The Austro-Hungarian Cavalry.**—The Austro-Hungarian cavalry was, according to the ideas and standards prevailing before the war, superbly trained. Officers, men and horses were first-class. But the ideas and standards did not survive the war. The Austro-Hungarian cavalry, however, prevailed, whereas the Russian cavalry, having absorbed the lessons of the most recent wars, rarely showed themselves in big masses, but worked in pairs or threes and used the existing cavalry, machine-gun detachments, artillery, and cyclists.

In 1910 Austria-Hungary had possessed eight cavalry divisions of the Common Army, to which in 1912 were added two Honved cavalry divisions, and on the outbreak of war a 9th Cav. Div. formed in the Austrian Landwehr. The regiments were: 15 Dragoon, 16 Hussar, 11 Ulan, 6 K.K. LWH. Ulia (these renamed mounted Schützen in 1917), 10 Hungarian Honved Hussar regts., and smaller units in Faro and Dalmatia. At the outbreak of war Hungary formed 10 Hussar half-regts. of Landsturm. In each regiment further 1st and 2nd reserve squadrons were formed. The bulk of this mounted force was grouped in 4 regts. at a regiment, the rest, including the reserve squadrons, allotted in pairs or threes as divisional cavalry to the infantry divisions or corps. The role of the cavalry divisions was exploration and screening, that of the divisional squadrons the local screening of the regiments. In both cases the performance of these functions met with unexpectedly great difficulties owing to the thoroughly modern tactics employed by the Russian cavalry, which employed all the methods of divisional fire fighting, and combined the same with energetic shock. This imposed at once a restriction in the cavalry methods of the Austrians. Little stress had been laid on fire fighting in peace, but when the war broke out the Austrian cavalry was not only scarce but became scarcer in 1917, mounted work fell more and more into the background. The equipment was revolutionized. The soldier was provided with wire cutters, grenades, obstacle material, etc. Already in the closing year of 1914 mounted work was given over to the use of trench warfare. The useless sabre was replaced by the bayonet. Thus, and in other ways, the arm rapidly adjusted itself to the new conditions. Even in the winter 1914-15 certain formations had
created dismounted sections, and these in time became the basis of Schützen divisionen of cavalry, analogous to infantry battalions.

In the winter 1917–18 a thorough reorganization was carried out. The regiment which at the outset had comprised 6 squadrons of 150 saboteurs each, with 9 mounted sections and 9 dismounted sections, was constituted on the basis of 2 half-regiments each of 4 squadrons dismounted; 2 machine-gun squadrons (8 guns each), 2 hand machine-gun sections and a technical squadron, besides an infantry gun section with 6 7.5-cm. howitzers, 1 2-lb. mortar section, and 1 minenräum section, and 1 searchlight squad, and 1 cavalry telegraph squad. The equipment of the individual man was assimilated to that of the infantry soldier. In each infantry and cavalry division there only remained mounted one squadron of divisional cavalry.

The cav. div., which had originally comprised 2 brigades, 4 regiments, 1–2 machine-gun detachments, and a horse artillery division (2 regiments), consisted of: a new basis of 4 brigade headquarters, 4 dismounted regiments, 1 storm regiment, 1 sapper section, one telegraph company (if required, one radio company) and one mounted squadron. From the available horse artillery foram be formed 1 mounted field artillery regt., each of 2 gun, 4 howitzer, and 1 trench mortar batteries. In 1918 it was planned to create brigades of horse artillery for the cavalry divisions, each consisting of one of the horse regts. and a heavy artillery regiment.

In March 1918 a 12th (mounted Schützen) Div. was created out of 4 regiments of that category.

Artillery.—No arm in any army was so completely transformed in the war as the horse artillery. Though worthy of its ancient reputation in point of science and training, it suffered at the outset from inferior material. Whereas Russia and Serbia taking to heart the lessons of Manchuria had modernized their guns, in Austria-Hungary these necessities were burked on political and financial grounds. It is true that the gun introduced in 1905 was a modern Q.F. equipment, equivalent to Russian and Serbian weapons of the same class, or at least the heavy horses. But the earlier company of 1893 which was, like the mountain guns and howitzers, obsolete and ineffective. Inadequate, too, was the fortress artillery. Apart from some 30-5-cm. mortars, mounted on the western front, and some 24-cm. mortar batteries, only quite obsolete guns were available.

In the year preceding the war, indeed, the most urgent necessity was the provision of means turned to the horse artillery. In the first place numerical increase was necessary. As against the 72–54 guns per division of other powers Austria-Hungary had only 42.

After various augmentations in the last two years the artillery consisted of 1700 guns of war, 8 mountain batteries, 240 howitzers of the Honved and Honved divisions; 28 army and 8 Landwehr field howitzer regiments (each of 2 batteries); 9 army and one Honved horse artillery regiments (each 3 batteries); 14 heavy artillery regiments (each 2 batteries); 10 mountain artillery regiments (each of 4 guns and 2 howitzer batteries), and 1 independent mountain division; 6 regimental field batteries.

During the war the development of the artillery was naturally ceaseless. It began with the replacement of old-pattern guns and increases in the available numbers of field guns. At the beginning of 1916 the 15-cm. howitzers, from 1915 field batteries, and the 21-cm. and 15-cm. weapons, and a modern 10.4-cm. long gun ranging to 12 km. was brought out. Further, two completely modern mountain batteries, each of 5 15-cm., 5-3-cm., 120-mm. howitzers (1915, ranging to 7 and 8 km.) gradually supplanted the older types.

In the course of the war the former ratio of howitzers to guns was greatly modified, till finally the former preponderated. In succession, batteries were taken from the field-gun regiments and re-formed in new howitzer regiments. The heavy howitzer divisions were augmented and in part armed with the new 15-cm. equipment, and, further, 11 10.4-cm. heavy-guns, batteries, as well as some heavy howitzer divisions still armed with 15-cm. guns.

By the end of 1915, the proportion of howitzers had come to be about 50%, and at the end of the war there were three times as many howitzers as guns.

Up to the end of 1915 the mountain artillery had been augmented by 5 regiments, the fortress artillery by one battalion, while the number of 30-5-cm. batteries increased to 20. At that date the formations of 30-5-cm., 25-1-cm., 15-cm., 120-mm., and 12-cm. guns howitzers (ranging to 18 and 12 km. respectively). At the beginning of 1916 all K.K. and Hungarian Landwehr howitzer batteries were grouped, by fours in the case of the light, in threes in the case of the heavy, in fours in the case of the medium, and in two sections of fours to the anti-aircraft artillery, which received modern as well as improvised weapons.

In 1916 there were: 28 army, 8 Landwehr, 8 Honved, 14 army reserve, 3 Honved reserve field-guns, 9 horse artillery divisions; 28 army, 8 Landwehr, 8 Honved, 14 army reserve, 4 Landwehr reserve, 3 Honved reserve field howitzer regiments; 15 anti-aircraft batteries; 30 army, 8 Landwehr, 8 Honved, 3 army reserve, one Honved heavy field artillery regiments; 28 army, 4 Landwehr, 3 Honved mountain artillery regiments.

At this period the introduction of 21-cm. mortars, of 38- and 42-cm. mortars and of 24- and 35-cm. long guns into the armament of the fortresses began. The long廊 gun Batteries were replaced by completely modern guns were motorized, and ranged to 15 km. in the case of the 24-cm. and to 36–32 km. in that of the guns. Twelve trench mortar batteries were also added to the fortress artillery.

The mountain artillery, badly unlateraled during 1917, the only noteworthy change being the transformation of the horse artillery already alluded to (summer 1917), the steady augmentation in the number of fortress batteries and the increased employment of mountain howitzer guns.

In connexion with the reorganization of the infantry divisions at the end of 1917 the artillery was of course recast also. In peace-time artillery was formed on the same basis as the mountain artillery. However, the field artillery regiments were established on the basis of 1 mounted field artillery regt., each of 2 gun, 4 howitzer, and 1 trench mortar batteries.

In the war infantry division had originally a brigade of artillery (one regiment field guns, one division howitzers). In Feb. 1917 the field artillery regiments were built up from one to two regiments, and three to four; the artillery regiments were uniformly reorganized with gun and howitzer batteries in each; and the designation "Field Artillery" was adopted by all. Each artillery brigade (one per division, i.e. 66) henceforth consisted of 2 field artillery regiments, one heavy field artillery regiment and one mountain artillery group. The field regiments had 2 guns and 3 howitzer batteries, and either a trench mortar or an anti-aircraft battery: the heavy and the howitzers, 1 gun, one only being armed with 10-4-cm. guns and the others with 12-cm. howitzers. The mountain artillery group had 2 gun and 1 howitzer battery.

The field artillery, with cavalry divisions, was similarly reorganized and gradually provided with heavy artillery units.

After providing for the above-mentioned mountain groups, there remained 14 independent regiments of that branch. These were composed of 1 Q.F. reserve, and each consisted of 6 guns and 3 howitzer batteries.

At the end of the war the field and mountain artillery of the Austr-Hungarian army amounted to a total of 864 light, 348 heavy, and 122 mountain batteries, as against 369 light, 28 heavy and 76 mountain at the outset.

The fortress artillery was also reorganized, and renamed "heavy artillery regiment, whilst its organization had varied according to its allocation to fortresses, but thenceforward it was formed in 14 regiments each of 4 groups at 4 batteries. On the verge of the Armistice 3 independent groups were created at Trieste, in Dalmatia, and in the South Carpathians.

Technical Troops.—In 1893 the previously existing engineer and pioneer corps were reconstituted as a single pioneer corps carrying out all engineer duties; this corps consisted of 15 battalions. In 1912 a new subdivision was introduced. "Pioneers" were allocated to water work and "Sappers" to land and fortress work—as had been the case before 1893. The pioneer corps then consisted of 8 four-company and 2 three-company battalions. At the same time special bridging battalion (for semi-permanent work) and a river-mining company were created. Both corps did their work well in the war, but they were far too small.

Each battalion of 1500 men, grouped in 15 companies, had the following special equipment: Halftrack lorries in existence, and the number of companies in each battalion had risen to 5 in the pioneer, 6 in the sapper battalions. The army was accommodated with the first anti-aircraft howitzers, anti-aircraft emplacements such as air raid columns and mobile parks. The bridging equipment consisted of 126 units, each capable of 53 miles of bridging.

The inadequacy of numbers was made good immediately after the outbreak of war by creating Landsturmb Sapper companies and numerous works detachments.

In the middle of 1915 a second bridging battalion was raised, and by the end of that year trench mortar, bombthrower and electro-technical units were in existence. The pioneer detachments had now increased to 200 companies and the sapper battalions, of the special bridging and mountain artillery type, were of 390. In 1917 all special battalions were formed for offensive gas warfare. Other technical and other special services were reduced, as they were unnecessary for the mining, powder-mining, bombthrower sections, compressed air, oxygen and air-liquefying stations; electro-technical matters (searchlights, live-wire obstacles, accumulators, drinking water and bridge-making) and small arms. The other thing, and these were constantly augmented.

The thoroughgoing reorganization of winter 1917–18 affected also the technical troops. The pioneers were abolished, and all technical battalions were replaced by a special bridging battalion, a special mining battalion, and, in the case of heavy field artillery, a special bridging battalion, and numerous bridging tool and other units. To the sappers now also went the well-boring and the electroweighty
formations. Searchlight units now consisted of one company (2 105-mm. guns). 45-mm. and 40-mm. were formed as a number of similar units under G.H.Q., and odd formations; further, each technical company or squadron of an infantry or dismounted cavalry regiment included a searchlight company.

Communication Troops.—Till May 1912 only one combined railway and telegraph regiment existed. This was divided at that date into two. The railway regiment consisted of 3 battalions, depot companies, and for telegraph companies, 3 railway companies at Przemysl, Cracow and Pola. The companies constituting these battalions were charged in war with the construction and maintenance of both types of railway road. Consisting at the outset of 30 railway and 4 railway operating companies, this branch had risen at the end of the war to a strength of 39 railways and 32 field railways companies. In occupied territories, the Austrian government took charge of many of the latter. A number were set up (Poland, Serbia, Italy, Rumania) which had at their disposal 8 operating railways and 28 operating companies. For transport in mountain regions (Alps, Rumania, Albania) there were 40 telpher operating and 9 telpher building companies. The light railway service consisted at the end of the war of 3 locomotive and 21 motor and 1 one horse operating sections, as well as 3 operating sections at Pola. Associated with the railway troops were some bridging detachments provided with iron-bridge equipment.

Lastly should be mentioned armoured trains. The first of these, an armoured locomotive, was improvised in 1914 to reconnoitre the enemy line and to act as a mobile garrison. At the outbreak of war the telegraph regiment consisted of 4 battalions, one radio detachment, depot cadre and an administrative unit for stores. This regiment was the parent of all telegraph and telephone units which constituted the basis of the Austrian radio service. The telegraph companies had to be regularized in the winter of 1917-18. The reorganization in that period reconstituted all telegraph and telephone units uniform in equipment and, to a large extent, in personnel. In the field, there were 159, as well as 65 line construction companies and 25 radio companies. Corps, army and higher headquarters had in all 72 radio posts, worked as 13 administrative groups, and there were 7 fixed stations for long-distance work.

Flying Corps.—Numerically Austria-Hungary was far behind other states in the numbers of her flying troops. Till a few years before the war only captive and free balloons were in use, chiefly in fortresses, and modern aeroplanes in Austria were practically followed only as a sport. However, a reorganization took place in 1913 which enabled the army to begin the war with one flying company of 6 machines at G.H.Q. and at each army headquarters, one dirigible balloon company, and depot units. As in other countries, necessity led to rapid developments from this nucleus. By the end of 1916 there were 37 flying companies allotted to the higher headquarters. In 1917 a special consideration of flying units according to their missions was begun; henceforward there were divisional companies for line and artillery work; deep reconnaissance companies, pursuit companies for air fighting, ‘big machine’ companies (bombers), proctor companies, depot and store of reconnaissance and photographic companies for map work. In Nov. 1918 the total of units was 82 flying companies, 32 balloon companies, 12 parks, 9 motor repair companies, and 1 balloon construction company.

Meteorological Service.—This was attached to the flying service, but provided for the requirements of all others as well, and was represented in all formations from divisions upwards.

Before the outbreak of war all the main lines of motor transport for military purposes was limited. For liaison duties between headquarters an Automobile Volunteer Corps and a Motorcyclists Volunteer Corps had been formed in Austria and an Automobile Volunteer Corps in Hungary some time before the war. But the first motor troops proper were created in the war itself, when the motorization of the train (ammunition, supplies, medical) and the necessity of regularizing the supply of cars, lorries, parts and fuel imposed this step.

At the outset only a very small proportion of the train was motorized, the lorries coming from private firms by way of requisition. On the other hand the army had the requisitioned lorries left by field troops and home service troops. The first named included by the end of the war 31 group commands and 238 auto columns, 39 ambulance columns, 10 postal columns. The auto troops at home were responsible for the issue of stores, apparatus, supplies of all kinds to the army and for the training of reinforcements.

Train.—The training of the transport corps (Train) in peace-time was limited to the maintenance of the lines of communication on ground proved, however, too heavy for the soft morasses of Galicia and Poland, and for the more forward echelons of transport local vehicles had to be requisitioned. On the other hand the special equipment of the Train in the field was taken from the mobile units, and the army was therefore responsible for the transport of the army and for the transport of bridging, postal, medical and other formations. The “division” itself remained at home as a draft and remount producing centre.

The expansion of the army naturally entailed corresponding developments which were accompanied by considerable reorganization in the winter of 1916-17. Simplification of supply procedure and the replacement of heavy military wagons by light vehicles of local types were the main features of this reorganization.

The reorganization of mountain troops had been carried further than any other state. At the outbreak of war there existed, as has been mentioned earlier, five mountain regiments of Austrian Landwehr (16 battalions) and there were intended a further 9 regiments for the Italian Alps. But in 1914 they were used against Russia, Serbia and Montenegro like any other regiment without regard to their special characteristics. And although in the summer returned to the Italian theatre, they were afterwards special army units during the war, though reinforced by a number of locally raised units. 1 Thus the mountain troops were organized into special regiments, of the borders, the regions, and mountain service, and were numbered like the other infantry, and were to be organized, in the mountain districts, as had been done in the Central Alps (these last units having been more or less a specialized fraction, should be adaptable to hill warfare.

1 Of these the best known were the village riflemen of the Alps; these, known as Sanbeschützen, formed the South Tirolese, Tiroler, Carinthian, Salzburg, Vorarlberg, Salzburg, Vorarlberg. Volunteer rifle units were raised also in 1917-18 under the leadership of the district Monarch.
cavalry, 1 Schützen cavalry (Landwehr), and 2 Honved cavalry divisions.

A division or subdivision of infantry divisions into brigades of two regiments remained unaltered; the cavalry divisions, however, after the reconstitution retained as a rule only one brigade staff. There were, however, as to the Austro-Hungarian Army, 10 Austrian Landsturm, 1 Hungarian Landsturm brigades, and 11 army cavalry, 1 Schützen cavalry and 1 Honved cavalry brigades.

The number of field artillery brigades had grown to 66. The best organized of this artillery was a corps (heavy) artillery which had practically disappeared.

Army.—The foreseen organization of the forces was in six armies, for which six general officers were designated in peace and functioned as superior commanders from Oct. 1914 to July 1915. The first-Rhine Bavarian—organized in the E. Carpathians; this became the VII. Army later. In Dec. 1914 the V. and VI. Armies in the Balkan theatre were dissolved and formed the "Balkan Army.

In May 1915, when Italy came into the war, three new armies were created—a new V., the army group Rohr, and the Tirol Defence Force—under the general command of a commander-in-chief S.W. von Alten. About the same time the III. Army on the Russian front was dissolved, but a new III. Army was formed in the autumn for the operations under Mackensen in Serbia. This III. Army shortly moved to Tirol where, with a new XI. Army and the Tirol Defence Force it constituted a group of armies for the Asiago offensive. Shortly after that the III. Army moved again, this time to the Russian front to aid in meeting Brusilov's offensive; here, with a new XII. Army, it constituted the Russian Army's group of armies.

On the entry of Rumania into the war a new I. Army was created. The former I. Army on the Russian front had been dissolved in July 1916. The Italian front the Rohr group had meantime become the X. Army, and the Tirol Defence Force was dissolved.

In the winter of 1917, after the Caporetto offensive, a new VI. Army was created to replace the departing German XIV. Army. This V. Army was formed from the six corps of the Isonzo; for this army this subdivision into the I. and II. Isonzo Armies, forming the Borovic group of armies, while the X. and XI. Armies constituted the Codor group of armies.

In the E. nearly all armies were dissolved during 1918, first the I. then the III., IV., VII. The higher command on this side was then shared between the I., IV. and VII. "General Kommandos." The Habsburg Army, however, continued to be known by its historic name and to the Armistice, under the name of K.u.K. Eastern Army.

In Albania, meanwhile, the Austro-Hungarian forces had been constituted as the Këves army group. On the breaking of the Ferdinand front in the autumn 1917, all available forces were constituted as one group of armies under the same general.

The End.—In Nov. 1918 the old Habsburg Empire dissolved in ruin, and with it the famous old army which had maintained its integrity through four years of trial. Its remnants formed nuclei for the national armies of the successor states. Its record was closed, and it passed into the eternity of history. (A-K; E; J.)

X.—The Turkish Army

At the time of the Balkan War mobilization in 1912, Turkey possessed an army in which the officer corps represented the traditions of the Sultan 'Abdul Hamid. Everything that might make for modern efficiency in war had for 30 years been excluded from the Turkish military curriculum. Ninety-five per cent of the rank and file were illiterate; their main virtues were willingness and endurance. The officers also were in the main untrained; they were drawn either from the stupid and hidebound ranker elements (Alali) or from the more up-to-date products of the military schools (Mektebi); but even these latter, mostly scions of better-class families, had little sense of accuracy and punctuality in the performance of their duties. There were, however, several staff officers who could neither read nor write. The Young Turkish movement had the effect of placing more energetic men at the head of the troops, but had also increased military avariciousness to such an extent as to become a positive danger to the army, and to make promotion hopelessly dependent, not on efficiency and professional skill, but on political intrigue. The redeeming feature of the army was the quality of the private soldier, and particularly of the Anatolian peasant. No troops in Europe were more steadfast, self-sufficient and patient. The Anatolian army had already proved that the Kurds useless in face of the enemy and as helpless as children, the Christian and Jewish subjects of Turkey of no military value.

The term of service in Turkey was three years for all arms. Mahmud Shevket Pasha has stated that 240,000 men per year became liable for service; of these some 110,000 to 120,000 were exempted, and of the rest only about 70,000 were actually enrolled. Official returns showed that out of a total pop. of 24,000,000 (of whom at most 15,000,000 were liable for service) men from 20 to 35 who were in age numbers about 4,000,000. The paper strength of this peace army showed 20,000 officers and 280,000 men. The total war strength of Turkey was estimated at 900,000 men of which about 400,000 were in the ranks of the Nizam units to war strength; this process usually absorbed them all, as the peace strength of the battalions was only 120, for the war 250. The system was to form separate and complete divisions, organized in their local recruiting areas. Any man liable to service could be released after three months on payment of £30 purchasing-out fine, and was there-
necessary radical alterations in their entirety. In view of the loss of territory consequent on the Balkan War, it was necessary to re-model the whole peace organization of the army, and to distribute it over the new area of the empire.

The total peace strength was now on paper 17,000 officers and 250,000 men, with 15,000 guns and 430 machine-guns; actually these numbers were never even approached. To each division was allotted 10,000 men in an area of 2000 square miles. The establishment after the German model, but did not effectively get to work prior to the World War. The organization of Redif divisions was also taken over, but the actual men who had served in service were to form these units, which were to be utilized in time of war to complete the first line units to full strength. Great importance was rightly attached to the institution of new military schools, the creation of an Armament Ministry, for the supply of which the German model had provided, and to the training of officers, for which purpose he had handed over command of the I. Corps. A new Army Act became law on May 12, 1914, but its provisions were never strictly enforced. Its principal clauses were: Every Turk, except for the suite of the Sultan's family, was liable to service from the age of 18. The period of service commenced on the March 1st next following the attainment of the age of 20, and extended over 25 years for infantry and train, for the other arms 20 years, and for the navy 17 years. The period of active service was in each of the above cases two, three or five years; students were allowed an abridged term; physically unfit men were liable to a special tax in lieu of service. Purchasing out was allowed at a rate, the total being divided between the State and the man. Thus liberated were transferred to the reserve and escaped all further liability for military duty in peace-time. Christian subjects of the empire were excluded from the ranks of the fighting troops. One was left the Ottoman. The great general staff was also entirely remodelled. German officers being placed at the head of the more important branches was those concerned with training, mobilization and intelligence.

Little or nothing could be done in the short space of time between the Balkan and European wars in the direction of rearming the army, so that the Turkish Armies in the Second Balkan War and the Great War armament and equipment were practically everything necessary for carrying on hostilities. Despite this German assistance the mobilization met with great difficulties. A Turkish War Office return in the summer of 1917 (which must, however, be treated with caution) gives the number of voluntary recruits called up from Aug. 1914 to March 1915, 1,014,824 from March 1915 to March 1916, and 332,000 from March 1916 to March 1917. Figures as to enrolments from this latter date onwards are very incomplete, as the total complement was not actually reached. The grand total of all who served in the Turkish army from 1914 to 1918 amounted to 3,000,000 men. If we take into consideration the facts that many of these were counted twice or three times over it may be regarded as approximating to reality to reduce this total to 2,000,000, of whom some 750,000 deserted and 500,000 were killed or invalided out of the service in the course of the war. It is of interest to note that the officials in Turkey were authorized by the War Office to take the law, always that all men called up—that is, rounded up by the police—as being of military age whether they were really so or not. Thus it happened that many young men were exempted as not coming within the age limit of 45, while in the course of the war a large number of men of 15 were given as being 20 or 30 years old, and therefore of military age.

The establishment of officers in the Turkish army reached its maximum of 50,450 in 1914, of which 7000 were officers, the remainder being at the front in 1915. The strength of the army, however, was at the time of mobilization, 1,085,621 in the previous spring. Despite great efforts and reckless use of all possible man-power resources, this total could not be maintained in 1917; in the spring of that year only about 300,000 men were present, and from that date on the total rapidly declined.

The organization of the supreme army command was also the work of the German military mission. This was in the hands of the chief of the German mission, General von Sanders, 1, 11, III, IV. and VI. Corps, one cavalry brigade and one battery heavy howitzers; II. Army, Jemal Pasha, V. Corps and (from Sept. 6 1914) VI. Corps, cavalry as for the other armies, and all available heavy artillery; III. Army, Hasan Izzet Pasha and XI. Corps; IV. Army, Zeki Pasha (later Jemal), VIII. and XII. Corps. The other troops of the peace army remained for the time being unorganized in armies. But even with these few armies it was not possible to bring the troops up to full war strength with the reserves available; some companies were barely 100 strong even in Jan. 1915. During the later stages of the war Enver's policy of limiting the formation of small well-organized corps and armies was given up; new formations were constantly being ordered, and old ones broken up or remodelled. For these the available man-power, armament and equipment were insufficient, so that the whole army was constantly growing smaller. Thus the I. Army, which in 1914 was over 200,000 strong, had sunk by 1917 to about 3,000 men, and the II. Army by 1918 to 5,000 men, and in 1918 there were in Palestine three Turkish armies, none of which were stronger than an English infantry division. All the armies, corps and divisions, however, still kept up their enormous staffs.

The number of officers in the German military mission increased in 1914 from 1,000 to 2,000, in 1917 to 800; a large number of other ranks, mostly of the technical services, must be added. Of complete German units the personnel of a few batteries at the Dardanelles and the crews of several gun-boats were German, and Enver shrank from employing larger units, and in principle stood against it. Only the so-called " Yildekim" (known to the Germans as " E") Group consisted entirely of German troops.

ARMY MEDICAL SERVICE (UNITED KINGDOM).—The British Army Medical Service never had such a task imposed on it as during the World War, from which it emerged with its organization tested by fire. Its duties cover the care of the sick and wounded of the military forces, the prevention by the medical service of disease, and the personnel of the medical service, the maintenance and administration of military hospitals and the command of patients in them, the medical examination of recruits and invaliding of men unfit for further service, the education and training of its own personnel, and the strategical and tactical employment of a variety of medical units concerned with the collection, evacuation and distribution of casualties in war.

Until 1873 the functions of an Army Medical Service had been carried out by a regimental system under which military officers belonging to and were the uniform of the regiment into which they were gazetted, and under which many of the sick and wounded were cared for in regimental hospitals. Soldiers enlisted in the combatant ranks were trained in hospital duties and formed a Medical Staff Corps, but they were not under the command of the medical officers. In 1861 the " Medical Staff Corps" was changed to "Army Hospital Corps," but the pay and discipline of the men were directly under the command of the medical officer. In 1863 the “ Royal Medical Corps” was changed to “Army Hospital Corps,” but the pay and discipline of the men were directly under the command of the medical officer. In 1883 a committee under Lord Morley, after the Egyptian War, recommended that the Army Hospital Corps and the officers of the Army Medical Department should be formed into a "Royal Medical Corps," but this recommendation was not adopted at the time. A compromise was made by forming the officers into a body called the "Medical Staff Corps," and the men into a corps called the "Medical Staff Corps," their
original name. At the same time the officers of the Medical Staff took complete command over the personnel of the Medical Staff Corps, and their uniform was assimilated to that of the latter. Eventually, after considerable agitation on the part of the medical profession, Lord Lansdowne, then Secretary of State for War, announced, at a banquet given by the Lord Mayor of London on May 4 1855 to the medical profession, that the Medical Staff and the Medical Service in the line of the British Army would be coupled together, one corps, namely the Royal Army Medical Corps (R.A.M.C.), with military ranks and titles from private to colonel similar to those of other branches of the army. The ranks above colonel, however, retained the title of surgeon-general until 1918, when this title was abolished and replaced by that of major-general or lieutenant-general.

**Peace Organization**

**Administration.**—The director-general of the Army Medical Service is the administrative head. He has the rank of lieutenant-general. His office is a branch of the adjutant-general's department at the War Office. He is not, however, a member of the Army Council, but may be required to attend council meetings when his advice is desired on any special subject. His staff consists of a deputy director-general, who is a major-general, eight officers of the rank of colonel, lieutenant-colonel or major (some of whom hold temporary appointments only concurrent with their position as a deputy or assistant director), the director of the six directorates of the Royal Army Medical Corps, and colonels-on-the-staff or major-generals as directors of hygiene and pathology. The directors of hygiene and pathology have deputy directors, assistant directors and deputy-assistant directors of hygiene and pathology as assistants in their directorates. The administration of the Queen Alexandra's Imperial Military Nursing Service (Q.A.I.M.N.S.) also forms a branch of the director-general's office under the matron-in-chief assisted by two principal matrons and a nursing sister. In 1921 an inspector of dental services was added to the director-general's staff on the formation of the Army Dental Corps, and the rank of lieutenant-colonel was assigned to its director.

The director-general's administration is assisted by an inspector of medical services, who is either a colonel or major-general of the Army Medical Service. He visits all stations at home and overseas with a view to maintaining a uniform standard of training and efficiency. He reports to the adjutant-general.

In all commands at home and overseas the director-general is represented by deputy-directors and assistant-directors of medical services. In some of the smaller garrisons the senior executive medical officer acts in an administrative capacity without being provided as a deputy or assistant director. The staff of these administrative offices varies according to the size and importance of the command or the conditions under which troops are serving. Thus in the small garrisons in the tropics where medical research is of importance there is a deputy assistant director of hygiene and pathology, although the administration may be in the hands of a senior medical officer only. In India there is a special administration for the Army Medical and Indian Medical Service. Officers of the latter, when employed on military duties, are under the administration of a director of medical services, who is a major-general or lieutenant general of the Army Medical Service, but the administrative appointments of the subordinate military commands in India may be held either by Army Medical or Indian Medical deputy directors and assistant directors. In war establishments there is a director of medical services in the headquarters of each army, a deputy director with each corps and an assistant director with each division. On their staffs are representatives of the directors of hygiene and pathology and other assistants.

**Advisory Boards.**—Connected with Army Medical administration there are several advisory boards or committees composed of military and civil members. An Army Medical Advisory Board advises on general professional questions. It is presided over by the director-general and its members are two consulting physicians, two consulting surgeons and the officers of the Royal Army Medical Corps. An Army Hygiene Advisory Committee is presided over by the director of hygiene. Its members include an officer of the Royal Engineers (R.E.) and of the Royal Army Service Corps (R.A.S.C.), and military and civil sanitary experts. An Army Pathology Advisory Committee is presided over by the director of pathology and civil pathologists of eminence who deal with technical questions connected with research into the causes of disease. Queen Alexandra's Army Nursing Board, of which Queen Alexandra is president, is composed of the matrons-in-chief of Q.A.I.M.N.S. and Territorial Force Nursing Service, of matrons of some of the large civil hospitals and of ladies nominated by the government to represent the Voluntary Aid Detachments, and the Voluntary Nursing Service, and the Royal Red Cross. It consists of representatives of the War Office, the British Red Cross Society, Scottish Branch of the Red Cross Society, the council of County Territorial Nursing Committees and the Matrons' and John and St. Andrew's Almoners' and Nurses' Associations. These boards and committees meet at the War Office.

In the professional medical field the Army Medical Service consists of officers, warrant officers, non-commissioned officers and men of the regular, reserve, Territorial, and territorial force, and of the Army Dental Corps, together with the affiliated nursing services of the regular army and territorial force, and the voluntary organizations recognized by the British Government under Article 3 of the Geneva Convention of 1906. The ranks of officers and men are the same as for other branches of the service. Officers and other ranks of the regular R.A.M.C. are under an obligation to serve in any case of officers called into war; but only the officers served in India, where the duties of subordinate ranks are carried out by a special Indian establishment consisting of an Indian Subordinate Medical Service, an Army Hospital Corps assisted by the members of the Indian Medical Service.

The members of the Indian Subordinate Medical Service are Indian-born British or native of India educated in Indian medical schools. It consists of medical officers who are commissioned in the Regular Army Medical Corps, but who are trained for service with regimental and medical units, a special list of territorials for general hospitals and another for sanitary services. The rank and file of the regular R.A.M.C. consists of: the field medical officer and the medical officer, in which in 1921 there were 35, in addition to four depot companies. Eleven of the companies had their headquarters in overseas garrisons. Both at home and overseas the headquarters of R.A.M.C. is a field headquarters of one or more sub-headquarters, the medical officer of field headquarters being the medical officer in charge of a hospital. They provide detachments for smaller hospitals and general duty. The number in each company varies in accordance with local requirements. The normal establishment of the regular R.A.M.C. on the active list is approximately 1,100 officers and 3,800 other ranks, but this is greatly expanded in time of war by calling up reserves of every description. During the World War it had expanded to some 15,000 officers and 120,000 other ranks, in the

**Training.**—The depot for training the regular R.A.M.C. is at Aldershot. The Territorial R.A.M.C. is organized and trained on a similar plan in each of 12 territorial divisions by officers of the regular R.A.M.C., who act as adjutants of the schools. There is a R.A.M. College in London, where officers of the regular R.A.M.C. help in the training of apprentices and assistant officers and final instruction in military hygiene, tropical diseases and other professional subjects. Training in field duties is carried out in the form of staff tours, camps of instruction and medical manoeuvres. Training in sanitation is carried out in the medical school of surgery at Aldershot and in schools of hygiene established in commands.

**Military Hospitals.**—Military hospitals are established in all commands at home and abroad. They vary in size from large general hospitals, such as the Royal Victoria hospital at Netley with over 1,000 beds, to small depot hospitals and detention wards in outlying posts. The number of beds normally maintained in peace-time in the United Kingdom is approximately seven thousand. In the World War this number expanded to more than 364,000; or, including beds in all theatres of war, to over 640,000.

**Medical Stores.**—An Army Medical Service Stores is maintained at Woolwich, where they maintain a contact with manufacturers of medical and surgical material and equipment to all garrisons at home and overseas, with the exception of India, which has its own stores. Supplies are obtained by contract from manufacturing firms. They are distributed through the central stores at Woolwich.

**War Organization.**

The organization of the Army Medical Service for war does not come into existence until mobilization is ordered. Medical units, the equipment which is maintained for mobilization stores, are then brought into being by the assembly of personnel, material and transport at places of mobilization assigned to each unit. Three zones of medical work are recognized: The collecting zone, the evacuating zone, and the distributing zone. In these zones there are medical services for the collection, transport and treatment of sick and wounded, for the supply of medical
and surgical stores, and for sanitary duties. Sick and wounded are collected in the first instance by a regimental medical service and passed from it to the field ambulances of the divisions. They are cleared from the divisions by motor ambulance convoys, which convey them to casualty clearing stations, whence they are passed down the lines of communication by rail, canal or road to the permanent hospital bases, and from there by seagoing hospital ships to the hospitals in the United Kingdom. This system is the regulation one, and is employed in all the field units of the army. There are, however, also the reserve ambulance trains, which work back to the casualty clearing stations; the evacuating zone as the lines of communication down to the sea bases or to the United Kingdom, and the distributing zone as the area of the hospital bases and the home territory.

The Regimental Medical Service.—Each regiment of cavalry, battalion of infantry, brigade of artillery, ammunition column, squadron or bridging train of engineers and certain supply trains has an officer of the R.A.M.C. attached to it, together with a small detachment of R.A.M.C. other ranks for technical charge of water carts and water supplies. Sixteen men of the regiment are placed under him during battle as stretcher-bearers; and a non-commissioned officer and eight men, trained locally to perform this duty, are also under him. Wounded are collected to a regimental aid post, which is established by the medical officer in a shelter or protected spot near regimental headquarters.

There are two general classes of ambulances. The field ambulance is the one most generally used by the field troops, and is an improvisation for a short period of time. The other is the field hospital, a more permanent establishment, and is used when a regiment is in permanent bivouac. The former consists of two sections, the lights or ambulance section, and the general field hospital section. The lights is composed of a tent division, and are organized in two sections, each section being formed of half the tent and half the field division. In the latter division there are 18 stretcher detachments. They bring wounded back from the regimental aid posts to an advanced dressing station formed by one of the tent sub-divisions at a point to which wheeled transport can be brought. Wounded are conveyed from the advanced dressing station to a more permanent one, as a matter of distance back by the remainder of the field ambulance or by other field ambulances where there is less exposure to enemy fire than at the advanced dressing station. Formerly both classes of ambulance had each 10 horse-drawn ambulance wagons, six of which in cavalry field ambulances were light wagons, the remaining four being heavy wagons of the same type as the 10 wagons of the field ambulance. Motor ambulance cars replaced a proportion of the horse-drawn wagons after the British Expeditionary Force moved from the Aisne to the Flanders front in 1914. The ambulance transport of the cavalry field ambulance now consists of four motor ambulance cars and two motor ambulances of the R.A.M.C. The motor ambulance is seven motor ambulance cars and two heavy horse- drawn ambulance wagons. They are employed in battle in carrying wounded to the first-aid station from the advance dressing station. The wounded are then carried by motor ambulances to the rear, and go forward in advance of the former where it is possible to do so. Their carrying capacity is two lying or eight sitting in the light wagon or light ambulance car, and four lying or 12 sitting in the heavy ambulance wagons. The troops are divisional troops and come under the command of the assistant director of medical services of the division.

Motor Ambulance Convoys.—The first motor ambulance used by the British in war was organized at the end of Sept. 1914 during the battle of the Aisne. It was formed of ambulance cars sent from France by the War Office early in Sept. and was rapidly followed by similar cars from the United States. Light vehicles and ambulances by voluntary organizations. Previously the system by which sick and wounded were brought from the field ambulances to railhead was to load them in the lorries of the supply columns returning empty to refill. But the system was found to be too slow. The War Office throughout was of opinion that the ambulance, which is the motor of transport subjected the wounded to serious discomfort and jolting, and partly because the requirements of supply services and medical services were in conflict with one another. A motor ambulance convoy was formed, with ambulance cars and ambulance wagons. The command of this convoy was vested in an officer R.A.M.C. with R.A.M.C. personnel for medical duties, and a R.A.S.C. personnel, under an officer R.A.S.C., as drivers and mechanics. These men are off-duty or in the line, and usually in the proportion of one for each army corps of which the army is composed, and one as an army reserve. They are normally army troops under the control of the director of medical services, who are as a rule a colonel. The disposition of directors of army corps. Their function is to clear the field ambulance main dressing station of sick and wounded to casualty clearing stations at or near railheads, and to perform all other ambulance transport duties by road not carried out by the transport of field ambulances. In the event of railway transport breaking down or proving insufficient to relieve congestion of sick and wounded in the front areas, motor ambulance convoys may be employed for conveying sick and wounded to hospitals at the base.

Casualty Clearing Stations.—These are medical units which form the transition between the evacuation zones, or between the divisions of the field army and lines of communication. Their function is to receive the sick and wounded from the divisional field hospital, and to continue the period of treatment as long as is necessary for further transport. The remaining sick and wounded, after receiving temporary medical and surgical treatment, are evacuated either by rail, canal or road, by motor ambulances of the R.A.M.C. hospitals at the base. Casualty clearing stations are consequently organized with a convalescent or lightly wounded section, a hospital section, and an evacuation section. Casualty clearing stations allotted to each division are in the proportion of one for each division, but they are essentially strategic units and are army troops, the director of medical services being responsible for placing them. They may not have any casualties, although they may be wounded anticipated in battle. They are mobilized with personnel and equipment for the care of 200 casualties at a time, but are capable of expansion to any extent in the field from local resources or by bringing up additional equipment and stores from the base, whenever the nature of the operations admits of this being done. The organization of casualty clearing stations, therefore, depends very much upon the service of the personnel of the station, and the number of casualties which it is possible to treat in the proportion of one for each division in the field, but their number depends on the length of the journeys from front to base and the time taken to return. Improvised ambulance trains are made up of passenger cars and other vehicles which can be procured for the purpose.

The ambulances were of this kind at the beginning of the World War, and were organized to carry 300 lying down on 600 sitting. They are commanded by an officer of the R.A.M.C. and are administered by the director of medical services on the lines of communication, whose staff regulate their journeys in association with the railway transport staff and in accordance with the demands of the army. They are mobilized as a rule in the proportion of one for each division in the field, but their number depends on the length of the journeys from front to base and the time taken to return.

field. They are situated at or near the sea bases but may be established for other hospital service centres elsewhere on the lines of which good transport communication is available. The stationary hospitals are smaller in numbers than the general hospitals and are organized for 200 or 400 beds. They are intended to act as local hospitals for the sick of large camps or other temporary establishments, and for the treatment of special cases requiring hospital treatment and graduated physical training. There is no fixed limit to the number or size. During the World War a convalescent depot could accommodate from 1,000 to 5,000 men.

Convalescent Depots.—These form large camps at the bases or elsewhere where convalescents on discharge from hospital are made physically fit to return to duty by convalescent establishments.

Mobile Laboratories.—For special work in the field four classes of mobile laboratories are organized. Mobile hygiene laboratories for chemical analysis of water and food supplies and for other hygienic purposes are allotted to the sanitary sections of the field army. Mobile bacteriological laboratories for medical and surgical bacteriological investigation are allotted in the proportion of two to each field army, and a mobile dental unit, in the proportion of one to each attached hospital. These laboratories are constructed on motor chassis and can be placed in any area as required. Mobile medical stores are employed in all the general and stationary hospitals, in ambulance trains and flotillas, hospital ships and casualty clearing stations.

Voluntary Organization in War.—Voluntary aid detachments of men and women are organized by the county territorial defense associations by county directors of the British Red Cross Society or St. John Ambulance Association. They have a definite composition of officers and men and are placed under the control of the War Office. On mobilization they undertake the opening and staffing of mobile hospitals, residences in the United Kingdom and the local transport of patients who are being distributed to hospitals in the United Kingdom. Members of women's detachments are attached to the hospitals employed in nursing duties in military hospitals. In theatres of war the function of voluntary aid organizations is to maintain stores for supplementing hospital equipment and supplies by articles which may add to their comfort and appearance, and by distributing gifts. Medical units offered by voluntary services or private individuals are not recognized unless they are organized on the same lines as corresponding regular units and under the command of officers of the R.A.M.C. In addition to the voluntary detachments, the St. John Ambulance Brigade and the St. Andrew's Ambulance Association maintain a home hospital reserve, the personnel of which are placed under the reserve list of the regular army hospitals in the United Kingdom when the latter are mobilized. Mobile hospital units were established at the beginning of the war in 1914. The St. John Ambulance Brigade had ready a home hospital service by the end of the year, and the St. Andrew's Ambulance Association 113, but these numbers increased so rapidly that by the end of 1915 over 15,000 of the St. John Ambulance Brigade were serving in the military hospitals in Great Britain. (W. G. M.)

UNITED STATES

Functions.—By Army Regulations the Medical Department in 1910 was charged with the following duties: Investigating the sanitary conditions of the army and making recommendations with reference thereto; organizing, maintaining, and operating all the hospital service, the selection and purification of water supplies, and the disposal of wastes; caring for the sick and wounded; making physical examinations of officers and enlisted men; managing military hospitals; recruiting, instructing and controlling the enlisted force of the Medical Department and the Nurse Corps; and furnishing all medical and hospital supplies, except for public animals. In 1921 these functions persisted.

COMPOSITION

Medical Department.—In 1911 the Medical Department comprised the Medical Corps, Medical Reserve Corps, Dental Corps, Hospital Corps (male), and Nurse Corps (female), to which could be added the Army Medical Corps, attached to the War Office, under the charge of the Medical Director. By the Act of 1916 provided that the Department should consist of “one surgeon-general . . . who shall be chief of said department, a Dental Corps, a Veterinary Corps, an Enlisted Dental Surgeon, and nine major surgeons . . . Subject to the appointment of great numbers of officers in temporary grades up to and including that of major General, as authorized by war legislation, this Act covered the organization of the medical service during the World War, with the exception that a new temporary body was formed which was known as the Sanitary Corps and consisted of officers and enlisted men, not possessing knowledge or experience of value to the Medical Department. The Act approved June 4 1920 stipulated that the surgeon-general should have the rank of major-general and should have two assistants with the rank of brigadier-general, the Secretary of War being the third assistant. Under this Act the enlisted strength of the Medical Department could not exceed 5% of the actual commissioned and enlisted personnel of the officers in the Medical Corps was fixed at 6.5 for every 1,000 of “authorized” (virtually actual) enlisted strength of the regular army.

As provided by Act of April 23 1908, the Medical Corps of the armed forces was composed of officers, a Captain, 52 majors, general, 14 colonels, 24 lieutenant-colonels, 105 majors and 360 captain-like first lieutenants, advancement being by seniority except in the case of lieutenants, who were promoted after three years' service. The scheme of promotion was modified on July 31 1919, by Act of 520 1920, to provide that officers of the Dental and Medical Corps should be promoted to the grade of captain after three years' service, to the grade of major after five years' service, to the grade of lieutenant-colonel after 20 years' service, and to the grade of major-general after 30 years' service, all subject to the satisfactory passing of the required examinations. On Oct. 1 1921 there were 43 colonies, 87 lieutenant-colonels, 52 majors, 245 captains and 211 lieutenants.

Beginning with 1901 the Medical Department employed civilian dentists under contract. The Act of March 3 1911 established a Dental Corps, consisting of lieutenants in the proportion of one to each 500 of the effective strength of the army, to increase to 60. By an Act approved Oct. 6 1917 the Corps was made to consist of officers of the same grades and proportionate distribution of grades as were then, or as might thereafter, be provided by law for the Medical Corps. The Corps, new branch, the Medical Reserve Corps, consisted of eight colonels, 15 lieutenant-colonels, 62 majors, 132 captains and 25 first lieutenants. The Veterinary Corps was established by the Act of March 3 1911, and comprised 12 colonels, 32 majors, 52 captains, 52 lieutenants and 43 first lieutenants. The Corps was established by Act of April 23 1908 for the purpose of securing a supply of medical officers available in emergency. The National Defense Act abolished the Medical Reserve Corps, as such, and established for an Officers' Reserve Corps, with sections corresponding to the various arms, staff corps and departments of the regular army. Under this law a medical section of the Officers' Reserve Corps, containing approximately 1,250 physicians, existed at the outbreak of the World War. On Oct. 14 1921 there were 5,816 officers enrolled in the medical section of the Officers' Reserve Corps, 3,747 in the dental section, 390 in the veterinary section, 264 in the sanitary section, 428 in the pharmacy section, and 136 in the medical laboratories. The Army Nurse Corps, composed of hospital stewards and privates, was established by Act of March 1 1897, which directed that all necessary hospital services in garrison, camp or field, including ambulance service, should be performed by members of the army, which was permanently attached to the Medical Department. The National Defense Act abolished the designation "Hospital Corps" and substituted the new title, Enlisted Medical Laboratory and Service Corps, private first class, and privates. The Army Nurse Corps (female) came into existence in 1901. No appreciable change in its organization was made until the Act of June 4 1920, when the members of the Corps were placed on war establishment. Promotions to the grade of major, the assistant superintendents that of captain, chief nurses that of first lieutenant, and head nurses and nurses of second lieutenant. In respect of matters within the line of their duties and within the period of the Corps' services, a first lieutenant was to rank with the major next officers of the Medical Department. Nurses in 1921 continued to be employed under contract for a period of three years, and did not receive the pay of their relative rank. The Medical
Administrative Corps was established by the Act approved June 4, 1864, to train cadets who must have enlisted service in the Medical Department. The duties of these cadets included the study of patients, examination of wounded soldiers, as well as the performance of duties relative to the immediate channel of the chief of staff. The surgeon-general advises the War Department in matters relating to his bureau, and on the subject of surgical matters to the general government. He is responsible for the instruction and training of all medical officers, registrars, property officers, commanders of detachments, and the like, in medicolegal duties, thereby relieving medical officers of the necessity of performing these essential but non-professional duties.

National Guard.—The organized militia, known as the National Guard, possesses a medical department consisting of a medical corps, dental corps, and various support forces; central personnel organization, discipline and equipment to like units of the Medical Department of the regular army. The personnel, known collectively as sanitary troops, is divided into three groups: (a) those assigned to combat units; (b) those assigned to support units of the medical regiments; and (c) those belonging to staff corps and departments.

Peace-time Organization

Surgeon-General's Office.—Whether in peace or war, the surgeon-general's office in Washington is one of the coordinate bureaus of the War Department which function under the Secretary of War through the intermediate channel of the chief of staff. The surgeon-general advises the War Department in matters relating to his bureau, coordinates all technical activities of the Medical Department through corps area or department surgeons, originates medical policy as to supply and disposal of equipment, personnel, camps and hospitals, establishes and maintains mobile medical units, and directs the provision of hospital services of the Medical Department to the soldiers, employees, and pensioners of the United States. The establishment of hospitals, the provision of hospital services, and the coordination of the administration of these activities are functions of the Surgeon-General's Office.

Communications Zone.—The chief surgeon of this zone, as a member of the staff of the commanding officer thereof, exercises immediate control over the Medical Department of the station and general hospitals, supply depots, training schools, central laboratories, hospital trains, boats and ships, ambulance parks, etc. The organization of the Medical Department at these stations, and the coordination of the medical, sanitation, and supply service, are functions of the Surgeon-General's Office on the basis described above for the surgeon-general's office.

Army Medical Service

War-time Organization

Object of the Medical Department in War.—The objects of the Medical Department administration in war are: First, the preservation of the strength of the army in the field by (a) the institution of requisite sanitary and medical regulations; (b) the retention of effective at the front; and (c) the prompt success of the offensive on the battlefield and their removal to the rear, thus preventing the unnecessary withdrawal of combatants from the firing line to accompany them. Second, the care and treatment of the sick and injured in the zone of the advance, on the line of communications, and in the home territory. Third, the promotion of general moral among the troops through the knowledge that efficient medical and surgical attention is immediately available.
